1 **Abstract**

2 **Background:** International comparisons of stillbirth allow assessment of variations in clinical practice
3 to reduce mortality. Currently such comparisons only include stillbirths from 28 or more completed
4 weeks of gestational age which underestimates the true burden of stillbirth. With increased
5 registration of early stillbirths in high income countries we assessed the reliability of including
6 stillbirths before 28 completed weeks.

7 **Methods:** We used national cohort data from 19 European countries participating in the Euro-
8 PERISTAT project on live births and stillbirths from 22 completed weeks of gestation in 2004, 2010
9 and 2015. Pooled stillbirth rates were calculated using a random-effects model and changes in rates
10 between 2004 and 2015 were calculated using risk ratios (RR) by gestational age and country.

11 **Results:** Stillbirths at 22⁺⁰-27⁺⁶ weeks of gestation accounted for 32% of all stillbirths in 2015. The
12 pooled stillbirth rate at 24⁺⁰-27⁺⁶ weeks declined from 0.97 to 0.71 per 1000 births from 2004 to
13 2015, a reduction of 24% (RR=0.77, 95% CI 0.68 to 0.88). The pooled stillbirth rate at 22⁺⁰-23⁺⁶ weeks
14 of gestation in 2015 was 0.53 per 1000 births and had not significantly changed over time (RR 0.97,
15 95% CI 0.80 to 1.16) although changes varied widely between countries (RRs 0.62 to 2.09). Wide
16 variation in the percentage of all births occurring at 22⁺⁰-23⁺⁶ weeks of gestation suggest
17 international differences in the ascertainment.

18 **Conclusions:** Current definitions used for international comparisons exclude a third of stillbirths.
19 International consistency of reporting stillbirths at 24⁺⁰-27⁺⁶ weeks suggests these deaths should be
20 included in routinely reported comparisons. This would have a major impact, acknowledging the
21 burden of perinatal death to families, and making international assessments more informative for
22 clinical practice and policy. Ascertainment of fetal deaths at 22⁺⁰-23⁺⁶ weeks should be stabilised so
23 that all stillbirths from 22 completed weeks of gestation onwards can be reliably compared.

24 **300 words**

1 Introduction

2 The 2016 Lancet stillbirth series highlighted the global impact of stillbirths on parents and families¹
3 with around 3.5 per 1000 births ending in stillbirths in high income countries^{2,3} and a decline over the
4 last decade for stillbirths in the third trimester^{2,4}. However, the full extent of the burden is generally
5 underestimated since a gestational age cut-off of 28 completed weeks for comparing the stillbirth
6 rate has been implemented widely as recommended by WHO for international purposes
7 (http://www.who.int/maternal_child_adolescent/epidemiology/stillbirth/en/ Accessed 07/03/2017).
8 Although WHO recommends a threshold of 22 completed weeks for ascertainment of stillbirths
9 within countries, there are major discrepancies between countries in their registration legislation and
10 within countries in the implementation of their legislation. These inhibit reliable international
11 comparisons^{2,4,5} using this limit. There are also differences in legislation about late termination of
12 pregnancy and the extent to which late terminations are reported as stillbirths and can be
13 distinguished from them. These have a major influence on reported stillbirth rates at early
14 gestations, particularly at 22⁺⁰ to 23⁺⁶ weeks^{6,7}. In addition international differences in the perception
15 of viability may lead to differences in legislation about the registration of stillbirths and their
16 ascertainment at early gestations^{1,8}.

17 Because of the way these issues affect the comparability of stillbirth rates, there has been little
18 international comparison of stillbirths below the gestational age threshold recommended by WHO of
19 28 completed weeks. Over the past few decades, however, there have been consistent increases
20 within countries in reported numbers of babies born before 28 completed weeks of gestation⁹, and
21 dramatic increases in their survival rates, with most babies born alive at 25 or more completed weeks
22 gestation surviving¹⁰. Flenady et al.² highlight that depending on the definition, between 35% and
23 50% of stillbirths occur before 28 completed weeks of gestation. The Lancet stillbirth series
24 suggested that stillbirth rates at earlier gestations are not showing the falls seen at 28 completed
25 weeks of gestation and over and may possibly even be increasing², but international comparisons to
26 confirm this statement are lacking. By excluding these stillbirths, the burden of stillbirths in high
27 income countries could be seriously underestimated. This could therefore fail to acknowledge the
28 heartache suffered by many parents and their families experiencing fetal death or stillbirth¹¹.
29 Furthermore, by excluding these deaths, international comparisons are limited in their ability to
30 assess the overall burden of stillbirth and the variations in clinical practice and therefore to identify
31 best strategies for improving care.

32 Only through international studies, such as the Euro-Peristat project, that collect data on births and
33 deaths starting at 22 completed weeks of gestation using a standardised protocol, can cross-country

1 comparisons of stillbirth rates be made. This makes the case for consistent international reporting
2 practices for terminations of pregnancy and agreed definitions for reporting of stillbirths and live
3 births. Here we undertake analyses of data from the Euro-Peristat project on stillbirths from 22
4 completed weeks of gestation in 19 European countries to assess the additional burden of stillbirth at
5 early gestational ages and to quantify changes in stillbirth rates at these early gestations over time.
6 These analyses will also compare the consistency of the reporting of fetal deaths by gestational age
7 to assess the evidence for moving the gestational age cut-off for the international reporting of
8 stillbirths in the future.

9

10 **Methods**

11 *Data sources*

12 The data from this study are from the Euro-Peristat project, which developed a list of valid and
13 reliable indicators for monitoring and evaluating perinatal health in the EU ^{4,5,9,12}. The Euro-Peristat
14 project collected national level data from routine population-based sources on its indicators in 2004,
15 2010 and 2015 using a common data collection instrument. Data come from medical birth registers,
16 civil registration, child health systems and routine surveys, as described previously.^{4,5,9,12} In 2004, 26
17 countries participated in Euro-Peristat, rising to 29 in 2010 and 31 in 2015. The project was based on
18 aggregated data collected routinely in each European country, following the ethics approval required
19 locally.

20 In this study, we use aggregated data on the numbers of live births and stillbirths by gestational age
21 for the years 2004, 2010 and 2015 for countries with data from all three periods, provided in a
22 comparable manner for the same geographic area. We excluded countries without national data on
23 stillbirths by gestational age in these periods (Cyprus, France and Spain), or where data available
24 were not comparable between 2004 and 2015 (due to changes in birth and death registration in
25 Sweden and Slovakia; due to lack of national data in 2004 in Belgium). We also excluded those
26 countries with fewer than 10000 births per year as the proportion of stillbirths at 22⁺⁰-27⁺⁶ weeks of
27 gestation is small and consequently the numbers of these deaths are extremely small (Malta and
28 Luxembourg). For the UK, data were provided separately for England and Wales combined, Northern
29 Ireland and Scotland. Thus, 16 countries were included in the analyses of stillbirths at 22⁺⁰ to 23⁺⁶
30 weeks of gestation and 19 in the analyses of stillbirths at 24⁺⁰ to 27⁺⁶ weeks of gestation. For the first
31 period, data were for births in 2005 in England and Wales and for births in 2003 in Italy. In the latter
32 period, data from Poland were for 2014, not 2015. Data sources are provided in Table S1.

1 *Definitions and analysis*

2 The stillbirth rate was defined as the number of deaths before or during birth per 1000 live and
3 stillbirths. Stillbirth rates were calculated separately for each country, year of the study (2004, 2010
4 and 2015) and for each gestational age subgroups (22⁺⁰ to 23⁺⁶ weeks; 24⁺⁰ to 27⁺⁶ weeks and 28⁺⁰
5 weeks and over)¹². The fetus at risk approach was used overall and by gestational age so, for
6 example the rate at 24⁺⁰–27⁺⁶ weeks was defined as the number of stillbirths from 24⁺⁰ to 27⁺⁶ weeks
7 divided by the number of fetuses in utero at 24⁺⁰ weeks¹³. Terminations of pregnancy were excluded
8 from stillbirth rates in countries where they were included in the data source and could be
9 differentiated from spontaneous stillbirths. In order to calculate the overall stillbirth rate in each of
10 the time periods, pooled estimates were calculated with 95% confidence intervals (CIs) for
11 gestational age group in 2004, 2010 and 2015. Meta-analysis techniques were used to obtain the
12 pooled stillbirth rate. A random-effects model was fitted using the method of Der Simonian and
13 Laird¹⁴ to take account of variation between countries. The change in stillbirth rate over time was
14 calculated using risk ratios (RR) with 95% CIs for each gestational age group in 2015 vs 2004. Again
15 meta-analysis techniques were used to obtain a pooled RR using a random-effects model. We
16 explored changes in ascertainment of stillbirths by calculating the RR of total births rates in 2015
17 compared with total birth rates in 2004 by gestational age group.

18 Several sensitivity analyses were undertaken. For all analyses, the impact on stillbirth rates of
19 including only those countries where terminations of pregnancy before 24⁺⁰ weeks of gestation could
20 be excluded from the data was explored. We also assessed the impact of excluding stillbirths with
21 unknown gestations which were classified as being of 28 completed weeks gestation or above in the
22 main analyses. Finally, we compared the percentage of stillbirths occurring between 22⁺⁰ and 27⁺⁶
23 week gestation in 2015 in the 8 countries excluded from our study because they did not have
24 comparable data across the 3 periods (Cyprus, Spain, Sweden, Slovakia, Malta, Luxembourg, Belgium
25 and France) to assess their comparability with the main results.

26 Analyses were performed with Stata, V.14.0 SE (Stata Corporation, College Station, Texas, USA).

27 *Role of the funding source*

28 The funders of the study had no role in study design, data collection, data analysis, data
29 interpretation, or writing of the report. The corresponding author had full access to all the data in the
30 study and LS and JZ had final responsibility for the decision to submit for publication.

31

1

2 **Results**

3 Table 1 shows the percentage of stillbirths at 22⁺⁰ to 27⁺⁶ weeks of gestation in 2015. This shows that
4 32.0% of stillbirths overall would be excluded from stillbirth statistics when reporting only deaths at
5 28⁺⁰ weeks of gestation and over. This proportion ranged from 20% in Estonia to 51% in the
6 Netherlands. Table 1 also shows that only a few countries could not exclude terminations of
7 pregnancy in 2004, 2010 and 2015 as, for example, the Netherlands where terminations could not be
8 separated from spontaneous stillbirths. In most countries, inclusion of terminations of pregnancy
9 after 24 weeks of gestation was rare. For countries reporting data on spontaneous stillbirths only,
10 the highest rate of stillbirth at 22⁺⁰ to 27⁺⁶ weeks of gestation in 2015 was 37% in Norway. This was
11 similar to the rate in 2004 (30%) and 2010 (35%) [see Supplementary table S2 & S3]. The percentage
12 of stillbirths at 22⁺⁰ to 23⁺⁶ weeks of gestation in 2015 varied widely between countries representing
13 between 6% in Ireland and 36% in the Netherlands or to 23% in Hungary if excluding countries where
14 terminations were included. Less international variation was seen for stillbirths at 24⁺⁰ to 27⁺⁶ weeks
15 in 2015 where they represented between 12% in Latvia and 29% in Slovenia or 23% in Northern
16 Ireland if excluding countries where terminations were included. In 2004 the variation was less for
17 22⁺⁰ to 23⁺⁶ weeks of gestation births but similar for 24⁺⁰ to 27⁺⁶ weeks births (see supplementary
18 table S2 and S3).

19 The pooled estimate of the stillbirth rate at 22⁺⁰ to 23⁺⁶ weeks of gestation for the 16 countries in
20 2015 (Figure 1a) was 0.53 per 1000 births in 2015 (95% CI 0.41 to 0.66). The relatively high I-squared
21 value of 94% suggested variation between countries. Ireland reported a rate of 0.26 per 1000 births
22 compared to 1.73 per 1000 births in the Netherlands, a six-fold difference. This range was reduced to
23 0.26 to 0.69 when excluding countries where terminations were included, a three-fold difference. For
24 births at this gestation, the stillbirth rate barely changed over time from 0.56 per 1000 births in 2010
25 (95% CI 0.39 to 0.73) and 0.55 per 1000 births (95% CI 0.40 to 0.70) in 2004, see Figure 1a. In 2004
26 rates ranged from 0.15 per 1000 births in Portugal to 1.37 in the Netherlands, an approximately nine-
27 fold difference in the most extreme rates. Comparing 2015 with 2004, there was no change over time
28 in the pooled estimate of the stillbirth rate (RR 0.97, 95% CI 0.80 to 1.16) (Figure 1a) but the changes
29 over time ranged widely between countries, from 0.62 to 2.09. A sensitivity analysis was undertaken
30 which included only countries where terminations of pregnancy before 24⁺⁰ weeks of gestation could
31 be excluded (see Table 1). This showed that the pooled rate did not change significantly over time
32 (RR 0.87; 95% CI 0.72 to 1.06) and variation in the changes over time between countries reduced but
33 was still wide ranging from 0.62 to 1.26.

1 This variation between countries at 22⁺⁰ to 23⁺⁶ weeks of gestation contrasted with the patterns for
2 stillbirths from 24 weeks of gestation onwards. The pooled estimate of the stillbirth rate at 24⁺⁰ to
3 27⁺⁶ weeks of gestation in 2015 (Figure 1b) in the 19 included countries was 0.71 per 1000 births
4 (95% CI 0.58 to 0.84) with rates ranging from 0.43 per 1000 births in Finland to 1.77 per 1000 births
5 in Slovenia, an approximately four-fold difference, with a relatively high I-squared value of 93%.
6 However this range was reduced to 0.43 to 0.78 when excluding countries where terminations were
7 included and could not be separated from spontaneous stillbirths, a two-fold difference. Over time,
8 the pooled rate had declined substantially from 0.97 stillbirths per 1000 births in 2004 (95% CI 0.79
9 to 1.14) and 0.81 stillbirths per 1000 births in 2010 (95% CI 0.69 to 0.93) (Figure 1b), with rates in
10 2004 ranging between 0.54 per 1000 births in Germany and 1.62 in Slovenia, an approximately 2.5
11 fold difference in rates. This represented a significant reduction over the decade from 2004 to 2015
12 in the stillbirth rate of 23% (RR=0.77, 95% CI 0.68 to 0.88) (Figure 1b) with moderate variation
13 between countries ranging from 0.42 to 1.18. A sensitivity analysis restricted to countries where
14 terminations of pregnancy from 24⁺⁰ to 27⁺⁶ weeks of gestation could be excluded (for countries
15 included see Table 1) showed a similar reduction of stillbirth over time (RR=0.78, 95% CI 0.67 to
16 0.92).

17 Over the three periods, there was wide variation in births occurring at 22⁺⁰ to 23⁺⁶ weeks of gestation
18 as a proportion of all births (Figure 2a), ranging from a reduction of 30% in Lithuania to an increase of
19 187% in Portugal. Overall the proportion of births at 22⁺⁰ to 23⁺⁶ weeks of gestation increased by 14%
20 from 2004 to 2015 (RR=1.14, 95% CI 0.99 to 1.31). In contrast, there was far less variation in the
21 change over time at 24⁺⁰ to 27⁺⁶ weeks of gestation (Figure 2b). Overall there was a slight reduction
22 in births at 24⁺⁰ to 27⁺⁶ weeks of 10% (RR=0.90, 95%CI 0.84 to 0.96) and this varied from a reduction
23 of 43% in Northern Ireland to an increase of 9% in Germany and Italy.

24 Sensitivity analyses excluding stillbirths of unknown gestational age had minimal impact on the
25 percentage of stillbirths occurring between 22⁺⁰ to 27⁺⁶ weeks gestation increasing the percentage of
26 stillbirths from 32.0% to 32.4%. Nor was there an impact on rates and relative risks over time.
27 Further sensitivity analyses exploring the percentage of stillbirths between 22⁺⁰ to 27⁺⁶ weeks
28 gestation in 2015 for the 8 countries excluded from our study found very similar results (33.5%).

29

30 **Discussion**

31 We have used data from 19 European countries to explore stillbirths before 28 completed weeks of
32 gestation, a group that is often not included in international comparisons of deaths. This has shown
33 that around one in three stillbirths are not accounted for in standard stillbirth rates measured from

1 28 weeks of gestation^{1,2}. Stillbirths at 24⁺⁰ to 27⁺⁶ weeks represent around seven per 10 000 births
2 and are declining in a similar manner to stillbirths seen at later gestations in European and other high
3 income countries, although our data, similar to these other reports, reveal heterogeneity in trends
4 across countries^{4 12}. Stillbirths occurring at 22⁺⁰ to 23⁺⁶ weeks of gestation represent around six per
5 10 000 births. Stillbirth rates for these gestations have remained steady over time, but our
6 hypothesis is that this is likely to be related to improvements in the reporting of deaths at these
7 gestations as there was an increase in all births at 22⁺⁰ to 23⁺⁶ weeks gestation compared to a fall in
8 births at 24⁺⁰ to 27⁺⁶ weeks gestation.

9 Interpretation and implications for policy

10 Stillbirth rates at 24⁺⁰ to 27⁺⁶ weeks appear to be falling by the same proportion as stillbirth rates at
11 28 weeks of gestation onwards¹². The fall of 24% in stillbirths at 24⁺⁰ to 27⁺⁶ weeks is extremely
12 similar to that seen globally for stillbirths of 28 weeks of gestation and above for a similar time period
13 of 2000 to 2015¹ suggesting consistent improvements over time in the reduction of stillbirths from 24
14 completed weeks of gestation.

15 In contrast, we found no change in the overall rate of stillbirth at 22⁺⁰ to 23⁺⁶ weeks between 2004,
16 2010 and 2015. It is possible that rates of stillbirth have remained stable at this gestation but this is
17 contrary to all other gestational age groups. In recent years the gestational age when a baby is
18 perceived as viable has decreased with changes in the approach to early management of these
19 babies. For example until recently, the American Academy of Pediatrics Neonatal Resuscitation
20 Programme¹⁵ recommended that resuscitation should be withheld when the gestational age is less
21 than 23 completed weeks or a birth-weight of less than 400 grams, but this has now been amended
22 to recommend that resuscitation should be withheld only below 22 completed weeks¹⁶ and this is
23 supported by increases in reported survival in some countries. Consequently there has been an
24 increased tendency for resuscitation of babies born at early gestations^{17,18} and an increase in the
25 tendency to report babies as a neonatal death rather than stillborn^{18,19} in some countries in Europe.
26 At the same time, the increase in viewing these early births as potential live births may also have
27 increased the reporting of early stillbirths.

28 Our study suggests that to ensure that the magnitude of the burden of stillbirth is better understood
29 and to improve routine data for monitoring of the outcomes and management of extremely preterm
30 births, WHO's threshold for international comparisons should be lowered, at least for high income
31 countries. Mullan and Horton emphasised in the 2011 Lancet series on stillbirth that "to a mother
32 and father, a stillbirth is no less a tragedy than the death of a newborn baby or child"²⁰ and that
33 parents deserve "recognition of their loss and reassurance that an accurate record of it will add to

1 the global knowledge required to prevent future ones²⁰. As part of the Lancet 2016 stillbirth series
2 Heazell et al. emphasised the major economic and psychosocial consequences of stillbirth. To a
3 mother or father a second trimester stillbirth is no less a tragedy than a stillbirth from 28 completed
4 weeks onwards and these parents too deserve recognition of their loss and accurate reporting of
5 deaths to improve care in the future.

6 Strengths and limitations

7 A major strength of this work is the wide geographic coverage, the use of a standardised data
8 collection protocol and the ability to ensure that late terminations of pregnancies at or after 22
9 weeks wherever possible were disaggregated from the stillbirths so that they were not included in
10 the fetal death rate. Unfortunately terminations of pregnancy could not be excluded for a few
11 countries; these occur principally at 22⁺⁰ to 23⁺⁶ weeks in many countries and while increases in late
12 terminations of pregnancy could contribute to the changes over time²¹, sensitivity analyses showed a
13 similar increase over time for those countries where terminations could be excluded. While we had
14 to exclude some countries in the Euro-PERISTAT project that didn't have comparable data for all
15 periods, our sensitivity analyses support the generalizability of our results, as proportions of early
16 stillbirths in these countries were very similar.

17 Conclusions

18 The consistency in reporting of births over time at 24⁺⁰ to 27⁺⁶ weeks of gestation and the similarity
19 of reduction in the rate of stillbirth over time to births at 28 completed weeks of gestation and above
20 suggests that stillbirths at 24⁺⁰ to 27⁺⁶ weeks of gestation can be routinely included in rates of
21 stillbirth for international comparisons from now on. Improvements to ascertainment of stillbirths at
22 22 and 23 weeks of gestation within countries will allow the routine reporting of all stillbirths from 22
23 completed weeks of gestation onwards or even earlier internationally. This would lead to better
24 alignment of the gestational age at which stillbirths and neonatal deaths are reported as has already
25 been done in some countries such as the US, Canada and Norway⁸. Such changes would enable a
26 fuller acknowledgment of the burden of perinatal death to health services and families and allow
27 assessment of variations in clinical practice in order to improve care.

1 Research in context

2 Evidence before the study

3 Over the past decade there have been several systematic reviews and scoping studies that have
4 reviewed the literature in order to investigate the rates and risk factors for stillbirth internationally
5 and, specifically, in high income countries^{2,3,22}. The most recent review was published in the Lancet
6 stillbirth series in 2016²³. To update these reviews, we searched PubMed for international
7 comparisons of stillbirth published from Jan 1 2016 to the present using the search terms
8 “(international OR worldwide)” AND “(stillbirth* OR fetal loss* OR fetal death*)” AND “(rate*)” in
9 titles and abstracts. We only included studies in English. Research suggested that depending on the
10 definition, between 35% and 50% of stillbirths occur before 28 completed weeks of gestation and
11 that stillbirth rates at earlier gestations are not showing the falls seen at 28 completed weeks of
12 gestation and over and may possibly even be increasing but international comparisons to confirm
13 this statement are lacking. Research also highlighted international variation in reporting of deaths at
14 22 and 23 weeks as a stillbirth or neonatal death which could impact on reported rates of stillbirth,
15 neonatal mortality and preterm birth.

16 Added value of this study

17 We used data from 19 countries participating in the international Euro-PERISTAT project, that
18 collected data on births and deaths starting at 22 completed weeks of gestation in 2004, 2010 and
19 2015. This project used a standardised protocol with consistent international reporting practices for
20 terminations of pregnancy and agreed definitions for reporting of stillbirths and live births. We
21 estimated 32% of stillbirths were not identified using the gestational age cut-off of 28 weeks which is
22 recommended for international studies. The pooled stillbirth rate at 24⁺⁰-27⁺⁶ weeks declined from
23 0.97 to 0.70 per 1000 births from 2004 to 2015, a reduction of 24% (RR=0.76, 95% CI 0.67 to 0.87) in
24 line with that reported in international studies on stillbirths over 28 weeks gestation. The pooled
25 stillbirth rate at 22⁺⁰-23⁺⁶ weeks of gestation in 2015 was 0.54 and did not significantly change over
26 time (RR 0.97, 95% CI 0.81 to 1.16) but trends varied widely between countries (RRs 0.62 to 2.09)
27 with evidence of differing ascertainment between countries at these earlier gestations.

28 Implications of all the available evidence

29 Current definitions used for international comparisons exclude a third of stillbirths. International
30 consistency of reporting stillbirths at 24+0-27+6 weeks suggests that to ensure that the magnitude of
31 the burden of stillbirth is better understood and to improve routine data for monitoring of the
32 outcomes and management of extremely preterm births, WHO's threshold for international
33 comparisons should be lowered, at least for high income countries. This would have a major impact,
34 acknowledging the burden of perinatal death to families, and making international assessments more
35 informative for clinical practice and policy. Ascertainment of fetal deaths at 22+0-23+6 weeks should
36 be stabilised so that all stillbirths from 22 completed weeks of gestation onwards can be reliably
37 compared. Contrary to speculation, stillbirths at 24⁺⁰ to 27⁺⁶ weeks are declining in a similar manner
38 to stillbirths seen at later gestations in European and other high income countries. Stillbirths
39 occurring at 22⁺⁰ to 23⁺⁶ weeks of gestation have remained steady over time, but this is likely to be
40 related to improvements in the reporting of deaths at these gestations. Improvements to
41 ascertainment of stillbirths at 22 and 23 weeks of gestation within countries will allow the routine
42 reporting of all stillbirths from 22 completed weeks of gestation onwards or even earlier
43 internationally. This would lead to better alignment of the gestational age at which stillbirths and
44 neonatal deaths are reported.

Table 1: Total births at all gestations, number of stillbirths by gestational age, percentage of all stillbirths occurring at 22⁺⁰ to 23⁺⁶ weeks, 24 to 27 weeks and 22 to 27 weeks of gestation in 2015 and information on inclusion of terminations of pregnancy by country (N/A=Not available)
