## From crystal to crust: the Proterozoic crustal evolution of southwest Norway

### Nicholas Michael William Roberts

### Abstract

The geology of the Suldal Sector, southwest Norway, comprises exposures from three orogenic periods; the Telemarkian, Sveconorwegian and Caledonian. Telemarkian (~1500 Ma) basement rocks are interpreted to be the oldest crust in the region; these are intruded by Sveconorwegian granitoid intrusions (~1070-930 Ma). Crystalline nappe units overlie the Mesoproterozoic basement, and from reconnaissance U-Pb dating and zircon hafnium isotopes, are believed to comprise slices of the Mesoproterozoic Norwegian continental margin.

The Telemarkian basement comprises meta-plutonic/volcanic lithologies that represent the deformed upper crustal section of a continental arc - the Suldal Arc; U-Pb dating suggests this arc was active from ~1520 to 1475 Ma. Whole-rock geochemistry and hafnium and oxygen isotopes measured in zircon, suggest that arc magmatism recycled older continental crust (20-50% contribution) that had been mixed with mantle-derived material in the lower crust; the older crustal component comprised late-Palaeoproterozoic sedimentary material derived from the Fennoscandian continent. During the arc's evolution, dehydration of mafic source magma induced by heat from magmatic underplating, and subsequent melting of dehydrated crust enhanced by asthenospheric upwelling, allowed for the intrusion of iron-enriched tholeiitic magmas. The Suldal arc and by extension, the Telemarkia terrane, represent the last stages of continental crust formation within a retreating accretionary orogen that was active since ~1.8 Ga.

Based on whole-rock geochemistry, U-Pb, hafnium and oxygen isotopes in zircon, Sveconorwegian granite suites formed between 1.07 and 0.92 Ga, and are largely derived from ~1.5 Ga mafic lower crust with a limited contribution of juvenile mantle-derived material. The geodynamic setting of granitic magmatism evolved from supra-subduction, to overthickened crust, to thinned crust with possible lithospheric delamination. The varying geochemistry of the granite suites (I- to A-type) is controlled not by geodynamic setting, but dominantly by water content in the magma source. Sveconorwegian deformation in the Suldal Sector is bracketed between ~1069 and ~1047 Ma by intrusions of the Storlivatnet plutonic complex.

Acknowledgements

### Acknowledgements

First and foremost I'd like to acknowledge the person that started the ball-rolling, the late Prof. Tim Brewer. Tim's involvement in this project was unfortunately short-lived, however, his rigorous and comprehensive approach to Precambrian geology, applied with his consistently high level of enthusiasm and wit, have given me a want to succeed and excel and have provided motivation for this project that still continues today.

By agreeing to my supervision, Prof. Randy Parrish probably took on a lot more than expected, but has continued to provide a wealth of knowledge, assistance, constructive criticism as well as praise, and without his input this thesis would be an order of magnitude thinner. Dr. Mike Norry also found himself supervising this project, and continues to be a geochemical 'rock' that one can always bounce ideas off; perhaps more important though is the holistic ideology that influenced me under Norry's tutelage whilst I was as an undergraduate at Leicester.

If during this project Randy and Norry play the role of espoused fathers, then I would liken Steve Noble to an uncle: taking a background role, but always providing unrestrained praise and encouragement, and willing to drop anything to help. Matt Horstwood and Dan Condon have also played key roles in this project, having made sure that I actually had some data to write about. Also at NIGL I would like to thank John Cottle, Jenny Bearcock, Vanessa Pashley, Laura Howell and Adrian Wood for providing technical and analytical assistance. In Edinburgh I owe tremendous thanks to John Craven for enabling me to walk away from the Ionprobe with some useable data, having arrived with the worst prepared samples he'd ever let on the machine!

Mogens Marker and Trond Slagstad at the Norwegian Geological Survey provided indispensible support in my first field season, and have since provided useful discussion, as well as complete access to their samples and data which have been a great benefit to this project. Rich Walker, Rhys Langford and Chris McDonald are also thanked for their assistance in the field.

At the University of Leicester I would like to thank members of the analytical staff, Nick Marsh, Colin Cunningham, Rob Kelly and Rob Wilson, and also all of the academic, technical and administrative staff; everyone at Leicester has made life pretty easy going... it does rather discourage one from 'getting a real job'.

Acknowledgements

I would like to thank the attendees of the Sveconorwegian fieldtrip that formed part of the International Geological Congress in 2008. The trip provided a great insight into the quirks, unresolved debates, and pros and cons of Precambrian geology and geochronology of Scandinavia; there are too many people to list, but I would like to mention Bernard Bingen for many useful discussions, manuscripts and data. Thanks also to Quentin Crowley, Mike Flowerdew and the guys from BAS for making a long stay in Oslo more enjoyable through a fair amount of (expensive) beer-drinking.

I am grateful to my office mates at Leicester (Pete, Becky and Alex) for keeping the insanity to acceptably low-levels, with a distinctive lack of talking-shop, a passion for sharing gossip, and a keenness to whinge about... well anything that needed whinging about. During my 8 years at Leicester there have been too many other postgrads to name, who have provided support pastorally, academically, and most importantly at the bar. I thank you all.

Outside of geology, many friends have provided support, whether it be a jest about 'going time-travelling', the odd 'so aren't you finished yet?', or just taking my mind off (which was surprisingly hard) very old non-mineralised non-oil bearing non-distinctive grey rocks in Norway. Many friends and family still ask when I'm going to get a job, but if academia isn't classed as a real job, then hopefully the answer will continue to be never.

I owe a great deal to my parents, who have provided unchecked loving support, whether it be motivationally or financially (especially during the days when I believed I still didn't own enough climbing gear, or when my car needed fixing!). And finally I have to thank Abi, who has always given me the most encouragement and support, and for always being there.

Thank you

Nick Roberts

### Introduction

### **1.1 Background and rationale**

This thesis is essentially a regional geological study, and one that aims to determine the geological evolution of the continental crust that forms southwest Norway. However, a number of 'themes' form subtle undertones throughout this work; in their broadest context these are: how, when and where was the continental crust formed? More specifically, it is the relative amount of new continental addition versus recycling of previously formed crust, that forms the strongest theme within this thesis. Particularly focussed on is crustal growth versus recycling within accretionary orogens; crustal growth in this particular setting has been well-studied in modern examples, but has not until recently been applied to the whole Earth history (Cawood et al. 2009).

#### **1.1.1 Topical aspects**

How and when the continental crust form and the rate of its production over time are fundamental questions in Earth Science. Answering these questions however has proved difficult, for example the last four decades have seen continued debate over whether the volume of continental crust has remained essentially unchanged since the early Archaean (e.g. Armstrong 1968, 1981), or whether the volume of crust has grown through time (e.g. Moorbath 1978; O'Nions et al. 1979). A key feature in this debate, is the apparent episodicity of crust formation (or juvenile mantle addition to the crust); such episodicity was recognised some 50 years ago (Gastil 1960), but the origin of apparent rapid continental growth periods is still debated today (e.g. Belousova et al. 2009; Condie et al. 2009; Iizuka et al. 2010).

Proxies for the continental growth record such as U-Pb crystallisation ages of juvenile granitoids, and Hf model ages derived from detrital zircons, all feature a certain element of episodicity, with peaks in individual datasets often overlapping (Figure 1.1); these global peaks in crustal production have been used to constrain models of supercontinent and superplume formation, and the link between these two planetary processes (Condie 2002; Li & Zhong 2009). However, it is poorly understood as to how much the peaks in the continental growth record result from actual increases in the production of continental crust, or result from preservational bias (Hawkesworth et al. 2009; Bahlburg et al. 2009).

Recent estimates on growth and recycling at modern plate margins suggest that the global rates of removal of continental crust are similar to the rates of its generation at magmatic arcs (Scholl & von Huene 2007, 2009; Clift et al. 2009). This leads to the inference that the current volume of continental crust may have existed since 2 to 3 Ga (Hawkesworth et al. 2010). To establish the role

of preservational bias in producing the apparent peaks in crustal growth, it is useful to determine a record of when and where continental crust was added and recycled for each continent, and then compare these to obtain a global record. The timing and extent of continental growth within Fennoscandia will be discussed within this thesis.

Figure 1.1. Compilation of mineral ages (Gastil 1960), compared with ages of juvenile crust (based on Condie 2005), compared with a compilation of U-Pb ages of detrital zircons (based on Campbell & Allen 2008). Grey bars show the timing of supercontinent formation. Note the episodicity of all three compilations, and the correlation with supercontinent formation. Modified after Hawkesworth et al. (2009).

Convergent margins are complex systems, with various parameters such as the thickness of crust, rate of convergence, angle of convergence, and the width of subduction zone, (e.g. Schellart 2008; Schellart et al. 2008), all impacting on the relative amount of continental growth (i.e. mantle addition) versus continental recycling (i.e. subduction erosion, sediment subduction). Although determining such parameters for ancient subduction zones is fairly unfeasible, general geodynamic settings can be postulated using geochronological and geochemical data. The geodynamic setting of studied magmatic suites is thus discussed in this thesis, with the aim of both constraining the tectonic evolution of the region, and determining the tectonic settings which favour continental growth over continental recycling.

#### **1.1.2 Regional aspects**

Proterozoic terranes are exposed over large areas of the continents; crystallisation age compilations of these terranes show peaks at 1.9 and 1.2 Ga (Condie 1998), and the average age of the upper crust determined from Sm-Nd is 2.0 Ga (Miller et al. 1986). Therefore, the Proterozoic is an important time period to study crustal growth. The good correlation of palaeotectonics between the Baltic Shield and other continents, e.g. Laurentia and Amazonia (Karlstrom et al. 2001; Johansson 2009), makes it an ideal location to study Proterozoic crustal growth.

The Fennoscandian Shield (referred to here as Fennoscandia and often referred to as Baltica by previous authors) is thought to involve southwesterly growth and accretion of continental crust, with an Archaean core in the northeast and Mesoproterozoic terranes in the southwest (e.g. Gaál & Gorbatschev 1987). This study focuses on the furthest southwest and what was traditionally thought of as the youngest terrane within the shield, known previously as the Rogaland Vest-Agder sector (Berthelsen 1980), and more recently informally termed the Hardangervidda, Suldal and Rogaland Sectors of the Telemarkia terrane (Bingen et al. 2005b).

Parts of the Rogaland Sector have been relatively well studied as the area is host to the Rogaland Igneous Complex, which comprises a large anorthosite-mangerite-charnockite (AMC) suite. The Suldal and Hardangervidda sectors are relatively poorly studied however, with the oldest gneissic basement not having a known age until recently (Bingen et al. 2005b).

The idea that Fennoscandia grew by sequential accretion of terranes to the west and southwest has been argued against based on data that suggest older crust may exist in the Telemarkia terrane (e.g. Ragnhildsvet et al. 1994). Also, the existence of possible crustal sutures within SW Fennoscandia (Cornell & Austin Hegardt 2004), has lead others to infer that Telemarkia is an exotic addition to Fennoscandia that wasn't accreted till the Sveconorwegian orogen. These arguments formed the initial reason to conduct this study into the poorly known parts of southwest Norway, and they form a topic which is repeatedly discussed within this thesis.

### **1.2** Aims

Following on from the topical and regional aspects outlined above, the general aims of this study are outlined here:

Using U-Pb geochronology to constrain the timing of tectonothermal events in the Suldal Sector, SW Norway.

Using petrography and whole-rock geochemistry to determine the petrogenesis and tectonic setting of igneous basement rocks in the Suldal Sector.

Using in-situ isotope geochemistry to determine the contribution of mantle material to magmatic events.

Using U-Pb geochronology, isotope and whole-rock geochemistry, assess whether crystalline rocks within Caledonian nappe units correlate with exposed basement that they overlie, and/or with Caledonian nappes elsewhere in Scandinavia.

Using the results collectively, test and develop tectonic models for the Proterozoic geological evolution of southwest Scandinavia.

### 1.3 Outline

Chapters 2 to 8 form separate entitities, each with their own introduction and conclusions; repetition of methods and geological background is kept to a minimum. The reader should refer to Chapter 2 for a regional geological context and background information on the study area. Chapter 9 presents a synthesis of previous findings, as well as new data and ideas on relevant topics.

Chapter 2 presents the geological setting for further chapters, with a brief introduction to the regional geology, and a description of the study area's geology; the latter includes a summary of the field-based and petrographical findings.

Chapter 3 presents a U-Pb geochronological study of basement rocks within the Suldal Sector, using both LA-ICP-MS and TIMS methods. The use of a chemical abrasion method combined with laser-ablation geochronology to produce precise Precambrian U-Pb ages is investigated.

Chapter 4 presents whole-rock geochemistry of the Telemarkian (~1500 Ma) basement rocks in the Suldal Sector, and discusses the petrogeneses of magmatic suites of this age.

Chapter 5 presents hafnium and oxygen isotope analyses measured in-situ in zircons from Telemarkian age gneisses. The data are used to further elucidate the petrogenesis these rocks, and discuss their tectono-magmatic setting in relation to the evolution of the Fennoscandian continent.

Chapter 6 presents whole-rock geochemistry and in-situ hafnium and oxygen isotopes for Sveconorwegian (~1.07-0.93 Ga) rocks from the Suldal Sector; the data are used to constrain the petrogeneses and geodynamic setting of the different granitoid suites.

Chapter 7 presents a LA-ICP-MS U-Pb age for a metarhyolite from a supracrustal belt in the Telemark Sector that has not been previously dated. The origin of this supacrustal belt (Grossæ-Totak) and other 'interorogenic' (~1.45-1.15 Ga) units within SW Fennoscandia is discussed.

Chapter 8 presents a study of the age and provenance of the Caledonian nappe units found within the Suldal Sector (known as the Hardangervidda-Ryfylke Nappe Complex), using LA-ICP-MS U-Pb geochronology and in-situ hafnium isotope analyses.

Chapter 9 presents a synthesis of the conclusions determined in all of the previous chapters. An overview of the tectonic history of the Fennoscandian Shield is presented which combines previous models with the new findings discussed in this thesis. A discussion of continental growth is presented, and is centred around the model of a retreating accretionary orogen. The growth of SW Fennoscandia is also discussed in relation to global tectonics and continental evolution.

### **1.4 Presentations**

Parts of this thesis have been presented as the following presentations:

'SW Fennoscandia in the formation and break-up of Rodinia (1): 1.8 - 1.0 Ga crustal growth and Sveconorwegian reworking.' (Poster), *N. M. W. Roberts, T. Slagstad, M. Marker*, Rodinia Fermor Metting 2009, Edinburgh.

'SW Fennoscandia in the formation and break-up of Rodinia (2): insights from the Hardangervidda-Ryfylke Nappe System.' (Poster), *N. M. W. Roberts*, Rodninia Fermor Metting 2009, Edinburgh.

'Proterozoic crustal growth in SW Fennoscandia' (Poster), *Nick M W Roberts*, Goldschmidt 2009, Davos.

'Proterozoic crustal growth in SW Fennoscandia' (Talk), *Nick M W Roberts*, Crustal Evolution Janet Watson Meeting 2009, London.

'Mesoproterozoic crustal evolution of southwest Norway; 1.5 Ga arc magmatism in Telemarkia.' (Talk), *Nick Roberts, Tim Brewer (decd.)*, 33<sup>rd</sup> IGC 2008, Oslo.

<sup>c</sup>Mesoproterozoic crustal evolution of southwest Norway) (Poster), *Nick Roberts, Tim Brewer (decd.)*, Geocchemistry Group AGM 2008, London. U-Pb data that is cited in chapters 5 and 6 was presented as:

'Mesoproterozoic growth, rifting, drifting and continental collision in Rogaland, SW Sveconorwegian province' (Poster), *Slagstad, T., Marker, M. and Skår, Ø.*, 33<sup>rd</sup> IGC 2008, Oslo.

### **1.5 Data sources**

All data was collected by the author, except for a proportion of the whole-rock geochemistry in chapters 3 and 6, which was acquired by Trond Slagstad and Mogens Marker for the Norwegian Geological Survey (NGU), and some of the U-Pb data used in chapters 5 and 6, which was acquired by Trond Slagstad and Mogens Marker on the Nordsim instrument at Stockholm. Also, some samples were collected by Tim Brewer, these have been re-analysed by the author. Some of the hafnium and oxygen isotope data was acquired on zircons already dated by Trond Slagstad and Mogens Marker. The interpretation of geochemical data obtained from NGU, and the interpretation of hafnium and oxygen isotope data obtained on zircons not belonging to the author, including all interpretations and conclusions. Supervisors and collaborators did provide some general discussion on data quality, preliminary data interpretation, and the form and presentation of the thesis.

### The geology of the Suldal Sector, southwest Norway

### 2.1 Regional Geology

Fennoscandia is the northwest part of the East European Craton, and comprises an Archaean craton in the northeast, mantled by successively younging geological domains to the southwest (Gaál & Gorbatschev 1987). Southern Norway and southwestern Sweden comprise the Southwest Scandinavian Domain (SSD), which was reworked during the Sveconorwegian orogeny (1.15-0.9 Ga). Crustal growth of this domain has been attributed to Gothian (1.75-1.55 Ga; Gaál & Gorbatschev 1987) and Telemarkian (1.52-1.48 Ga; Bingen et al. 2005b, 2008a) events. During the Sveconorwegian orogeny, lithospheric-scale shear zones are inferred to have displaced crustal domains (Park et al. 1991; Romer 1996; Stephens et al. 1996; Bingen et al. 2001b, Andersen et al. 2002b) so that the pre-Sveconorwegian configuration of the continent is enigmatic.

The SSD is bound by the Transcandinavian Igneous Belt to the east, and by Caledonian nappes to the north, and has been split into lithotectonic domains which young from east to west. The Transcandinavian Igneous Belt (TIB) is a composite belt of igneous rocks that trends NNW-SSE through southern Sweden to the NW Norwegian coast. The belt is dominated by coarse-grained porphyritic granitoids. TIB magmatism is split into two episodes, TIB 1 (1.81-1.77 Ga) and TIB 2/3 (1.72-1.66 Ga; Åhäll & Larson 2000), with TIB 1 intruding Svecofennian crust and TIB 2/3 intruding TIB 1 crust (Åhäll & Connelly 2008). The tectonic setting of the belt has been debated but is generally considered to be related to subduction converging in a NE/E direction (see Högdahl et al. 2004). Andersen et al. (2009a) propose that the voluminous granitoids were produced by anatectic melting of juvenile Svecofennian crust, with voluminous deep crustal mafic intrusions acting as a heat source.

The Eastern Segment (or Kläralven-Aträn terrane) lies to the west of the TIB belt, but is considered to be an extension of the younger TIB 2/3 magmatic belt that has been reworked prior to and during the Sveconorwegian orogeny (Connelly et al. 1996; Söderlund et al. 1999). The Protogine Zone marks the boundary between reworked and relatively undeformed TIB crust, and is a zone of both Gothian and Sveconorwegian deformation (Larson et al. 1990).

The Idefjorden domain lies to the west of the Eastern Segment. The domain comprises gneisses and granitoids of Gothian and Sveconorwegian age, as well as units not found in other terranes within the SSD, e.g. 1.38-1.30 Ga granitoids (Åhäll et al. 1997; Austin Hegardt et al. 2007). Growth of the Idefjorden crust occurred in the Gothian by continental arc magmatism and accretion of island and back-arcs (Brewer et al. 1998; Åhäll & Connelly 2008). The arc-crust of the Idefjorden domain may have formed proximal to the Fennoscandian continent along the same subduction margin that formed the TIB 2/3 crust (e.g. Åhäll & Connelly 2008), or may represent an allochthonous crustal

domain that was accreted to the Fennoscandian craton during the Sveconorwegian (Cornell & Austin Hegardt 2004). The Mylonite Zone that divides the Idefjorden and Eastern Segment is a zone of Sveconorwegian deformation, related to early thrusting of the Idefjorden domain over the Eastern Segment, and later exhumation of the Eastern Segment via east-west extension (Söderlund 1999).

Figure 2.1. Map of the East European Craton, Precambrian domains within Fennoscandia and terranes within the Southwest Scandinavian Domain. After Bogdanova et al. 2008; Bingen et al. 2008a.

The Bamble and Kongsberg blocks are grouped together by Bingen et al. (2005b), who consider them to be a collision zone between the Telemarkia and the Idefjorden domains. The Bamble and Kongsberg domains both include gneiss and granitoids units similar in age and composition to the Telemarkia and Idefjorden terranes that bound them (Åhäll & Connelly 2008; Andersen et al. 2002b; Bingen et al. 2005b), i.e. subduction-related arc plutonics and volcanics of Hisingen age (1.59-1.52 Ga; Åhäll & Connelly 2008). Metasedimentary units within the domain were deposited between the Telemarkian and Sveconorwegian periods (de Haas et al. 1999, 2002; Bingen et al. 2001; Åhäll et al. 1998; Knudsen et al. 1997).

The crust west of the Bamble-Kongsberg domain has been grouped into a single terrane (Telemarkia; Bingen et al. 2005b) that comprises four sectors; the Telemark Sector in the east, and the Rogaland, Suldal and Hardangervidda Sectors in the west. The latter three forming the Hardangervidda-Rogaland Block of Andersen et al. (2005), or the Rogaland-Vest-Agder Sector of Berthelsen (1980).

The Telemark Sector features a >10km thick succession of supracrustals comprising the 1.5->1.35 Ga Vestfjorddalen, and 1.16-1.10 Ga Sveconorwegian Supergroups (Laajoki et al. 2002). The Vestfjordallen Supergroup comprises the bimodal 1.51 Ga Rjukan Group and the overlying sedimentary Vindeggan Group..Bimodal magmatism is related to continental extension that occurred inboard of a subduction zone in a setting similar to the Granite-Rhyolite provinces in the mid-continental US (Slagstad et al. 2009). The Vemork Formation that is part of the Rjukan Group is dominated by metabasalt units; an intercalated metavolcanite is dated at  $1495 \pm 2$  Ma (Laajoki & Corfu 2007). The 5km thick Vindeggan grous comprised mostly of quartz-rich strata; a crosscutting diabase intrusion dated at 1347 ± 4 Ma (Corfu & Laajoki 2008) places a minimum age constraint on sedimentary deposition within the group. The Sveconorwegian Supergroup comprises bimodal volcanic and sedimentary sequences deposited between 1.17 and 1.12 Ga (Laajoki et al. 2002; Bingen et al. 2003), that formed in extensional basins inboard of a continental arc (Brewer et al. 2004), or in a Basin and Range setting (Bingen et al. 2003). Intrusions in the Telemark Sector include 1.19-1.13 Ga A-type plutons (Bingen et al. 2003), and a 1.03 Ga suite transitional between calc-alkaline and A-type (Bingen & van Breemen, 1998). The Setesdal region is host to the oldest crust recognised in Telemark, the Asen tonalite (1555  $\pm$  29 Ma; Pedersen et al. 2009). The main group of gneisses in the Setesdal region have ages of 1.32-1.22 Ga (Pedersen et al. 2009). At 1.2-1.2 Ga, juvenile granitoids intruded the gneisses in the Setesdal region; in the Vråvatn Complex in central Telemark, juvenile magmatism is dated at ~1.2 Ga (Andersen et al. 2007b; Pedersen et al. 2009).

In the Hardangervidda Sector (Figure 2.1) a gneiss complex comprises metasediments interlayered with granitic gneisses, the latter has been dated at ~1.65 Ga (Ragnhildsvet et al. 1994). A quartzofeldspathic gneiss yields a bimodal distribution of zircon ages, initially interpreted as gneiss crystallisation at 1.67 Ga and migmatisation at 1.47 Ga (Sigmond et al. 2000), and later interpreted as a paragneiss unit (Bingen et al. 2005b). Detrital zircon populations from metasediments in the area include Archaean to Mesoproterozoic components, with deposition constrained to later than 1.54 Ga (Bingen et al. 2001).

The geology of the Suldal Sector (Figure 2.1) can be divided into two parts, the 'basement' and the autochthonous/allochthonous nappes of Caledonian age. The basement was originally divided into three parts, supracrustal belts, a gneiss complex, and igneous intrusions; with the latter being both older and younger than the supracrustals (Sigmond 1978). All of these rocks formed in three

Chapter 2 – Geology of the Suldal Sector

Figure 2.2. Geological map of SW Fennoscandia, (see Figure 3.1 for study area).

separate Proterozoic events. The gneiss complex, most supracrustals and many of the intrusions are dated between 1540 and 1480 Ma (Bingen et al. 2005b; Slagstad et al. 2008). One supracrustal belt, Sæsvatn-Valldall, is younger and formed at 1260-1210 Ma (Bingen et al. 2002; Brewer et al. 2004).

A few granitoid intrusions within the sector have Sveconorwegian ages (Andersen et al. 2002a, 2007a; Bingen et al. 2005b; Slagstad et al. 2008).

Supracrustal rocks in the Suldal Sector have been mapped as three belts: Grjotdokki-Nesflaten, Suldal-Åkrafjord and Sæsvatn-Valldall (Sigmond 1978). The Grjotdokki-Nesflaten belt has not been directly dated, but surrounding conformable gneiss dated at 1499  $\pm$  12 Ma, lead Bingen et al. (2005b) to interpret a ~1500 Ma age for the belt. Deformed porphyritic granodiorite gneiss lenses that occur in the Suldal-Åkrafjord belt are dated at 1497  $\pm$  12 and 1496  $\pm$ 12 Ma (Bingen et al. 2005b); the age of volcanism in this belt is thus also interpreted to be ~1500 Ma. The Sæsvatn-Valldall belt has a metarhyolite at its base dated at 1259  $\pm$  2Ma (Brewer et al. 2004), and a sandstone at its top that is younger than 1211  $\pm$  18 Ma (based on the oldest dated zircon grain; Bingen et al. 2002). The belt formed in a marginal continental setting (Bingen et al. 2002), probably in a back-arc environment (Brewer et al. 2004).

The Rogaland Sector (Figure 2.1) comprises similar Telemarkian (1.52-1.48 Ga) rocks to those found in the Suldal Sector. Metasedimentary units are commonly interleaved with orthogneisses in the Rogaland Sector (Slagstad & Marker pers. comm. 2008), whereas they are rare in the Suldal and Hardangervidda Sectors. Concordant and deformed amphibolitic sheets found within the Rogaland gneisses have a Large-Ion-Lithophile-Element enriched N-MORB type signature (Slagstad & Marker pers. comm. 2008), are interpreted to have formed in an ocean-forming rifting event prior to the Sveconorwegian collision (Slagstad et al. 2008). The ~1500 Ma gneisses in the Rogaland Sector are typically migmatitic and highly deformed; less-deformed gneisses and granitoids are also found within the sector which are ~1200-1220 Ma in age (Slagstad et al. 2008).

The Sirdal Zone (Slagstad et al. 2008) is a broad region dominated by porphyritic granitoids and leucogranites, including the 1050 Ma Feda suite (Bingen et al. 1993; Bingen & van Breemen 1998). The granitoids may have an origin as an active continental margin that existed just prior to Sveconorwegian collision (Bingen & Van Breemen 1998; Slagstad et al. 2008), or an origin from partial melting of pre-existing crust with an arc signature as a consequence of crustal thickening during the Sveconorwegian orogeny (Bingen et al. 2008c). The Sirdal Zone may have formed from the partial subduction of the Rogaland Sector under the Suldal Sector during the early stages of the Sveconorwegian orogeny (Slagstad et al. 2008).

Late-Sveconorwegian (i.e. post-collisional/post-kinematic) granites intrude all of the Sectors. A broad region of granite plutons extends north to south and parallel to the Mandal-Ustaoset Line that divides the Telemark Sector from the Hardangervidda-Suldal-Rogaland Sectors. This alignment has been related to granite plutonism along lithospheric weaknesses that formed during the Sveconorwegian orogeny (Bogaerts et al. 2003; Duchesne et al. 1999). The ~930 Ma Rogaland anorthosite complex (Schärer et al. 1996) is the youngest of the late-Sveconorwegian intrusions in the region.

The Suldal and Hardangervidda Sectors are overlain by the Hardangervidda-Ryfykle Nappe Complex (Andresen & Færseth 1982; see Chapter 7), which was thrust onto the basement during the Caledonian orogeny (e.g. Gee et al. 1975). The deformation of the basement related to this orogeny is minimal and limited to a zone (<10m) of weak shearing only seen in some places. Together the nappes and basement have been weakly folded into large open folds (Sigmond 1978).

Within the Suldal sector, metamorphism has been dated by the Re-Os method on Cu-Mo mineral occurrences (Stein & Bingen 2002), with rocks from the Sæsvatn-Valldall belt recording various stages of metamorphism and deformation: onset of greenschist facies metamorphism and deformation at 1047  $\pm$  2 Ma, peak ductile deformation at 1032  $\pm$  2 Ma, incipient extension/relaxation at 1025  $\pm$  2 Ma and full relaxation (and brittle deformation) at 1017  $\pm$  2 Ma (Stein & Bingen 2002). Within the RVA sector, high-grade metamorphism has been attributed to the intrusion of the Rogaland Igneous Complex (Tobi et al. 1985), it has now been shown that highgrade metamorphism occurred prior to the intrusion, and a UHT overprint was locally induced due to contact metamorphism from the igneous complex (Möller et al. 2002). Within the UHT isograd surrounding the Rogaland Igneous Complex, zircon growths believed to be metamorphic reveal high-grade metamorphism at 1000 Ma (M1), ultra-high grade metamorphism at 930 Ma (M2), and later high-grade metamorphism related to M2 at 910 Ma (M3) (Möller et al. 2002, 2003). Re-Os dating of molybdenite records granulite-facies metamorphism at  $973 \pm 4$  Ma, that probably resulted from regional decompression towards the end of a prolonged period of metamorphism (1.03-0.97 Ga) (Bingen & Stein 2003). The origin of regional/local metamorphism and structural deformation outside of the area affected by the Rogaland Igneous Complex, is not constrained, but has been postulated to be Sveconorwegian in age (Bingen, cited in Bingen et al. 2005b).

### 2.2 Geology of the Suldal Sector

#### 2.2.1 Description of units

The basement rocks (that are assumed to be 1540-1480 Ma in age) are predominantly grey orthogneisses that are variably deformed and recrystallised, and likely represent mid-crustal to supracrustal igneous protoliths. Primary contacts and igneous structures have been obscured by the deformation and recrystallisation, such that a lithostratigraphy and chronology of events is difficult to elucidate.

As stated above, the original mapping defined three separate supracrustal belts; however, banded fine-grained gneisses interpretable as supracrustal rocks outcrop throughout most of the Sector. The discrimination of the Suldal-Akrafjord belt as a separate unit is therefore abandoned; although, one sequence of banded fine-grained rocks that outcrops east of Sauda is distinguished as a separate unit. This belt, referred to here as the Zinc Mine Banded Gneiss, forms a coherent block of banded and layered gneisses that have a single structural fabric, and is bound by undeformed granites and

Caledonian nappes. A few samples were taken from the Grjotdokki-Nesflaten belt in the Nesflaten area, the term 'Nesflaten Suite' is used when referring to this study area.

#### Sauda Grey Gneiss

The term Sauda Grey Gneiss (referred to as Grey Gneiss) refers to the bulk of the crystalline basement rocks, except for undeformed to weakly deformed granitoids that are assumed to be Sveconorwegian in age, the Zinc Mine Banded Gneiss and Nesflaten Suites, and the amphibolite suite. The Grey Gneiss is a heterogeneous complex of orthogneisses, comprising gabbro, diorite, granodiorite and tonalite compositions, along with minor granite-syenite. The complex is dominated by fine to medium-grained porphyritic grey gneisses. Some outcrops feature banding, commonly between aphyric and phyric units, likely representing volcanic tuff/ignimbrite/lava (i.e. supracrustal) layers. Medium-grained porphyritic gneisses likely represent hypabyssal/upper crustal intrusions. Gneisses with evidence for a non-igneous epiclastic origin (i.e. paragneiss) were not observed.

Sauda Grey Gneiss orthogneisses comprise plagioclase, biotite, amphibole and varying quartz contents, with minor K-feldspar in more silicic compositions. Accessory phases include abundant titanite which commonly forms coronas around ilmenite, apatite, epidote in the more mafic lithologies, and zircon in the more evolved lithologies. The amphibole is a hornblende in more pristine samples, but is commonly retrogressed to actinolite. Alteration of feldspar to sericite is widespread in most samples and biotite is commonly altered to chlorite.

Enclaves are common within the grey gneisses, and are of variable lithologies. The most common are fine-grained mafic to felsic xenoliths within granodioritic gneisses, but also displayed are tonalitic/granitic enclaves in more mafic units, often interpretable as disaggregated veins/dykes. Some outcrops include evidence of magma mingling, the best example of this comprises aphyric granodioritic gneiss mingling with aphyric dioritic gneiss; margins between the two lithologies are rounded. Partial melting within the Grey Gneiss is evident in some outcrops, usually without large-scale separation of leucosome and melanosome. In a few outcrops, leucosomes of tonalitic material have formed a network of cm- scale veins which are normally sub-parallel to the structural fabric. A few outcrops of fine-grained banded gneiss exhibit patch-leucosome formation, with new growth of hornblende within the leucosomes.

#### Zinc Mine Banded Gneiss

The Zine Mine Banded Gneiss (ZMBG) is a succession of fine to medium-grained banded gneisses that outcrop in the valley east of the town of Sauda. Compositions range from basalt to rhyolite, but the suite is dominated by dacitic to rhyolitic compositions. The gneisses are commonly porphyrytic with <10mm size phenocrysts of K-feldspar and quartz, in thin-section these are often aggregates of both quartz and feldspar. Interlayered and conformable with fine-grained gneisses are a few 10cm's

to <50m layers of coarse porphyritic granodiorite (augen gneisses). These are interpreted as hypabyssal intrusions which are likely to be comagmatic with the surrounding gneisses. The mineralogy of the ZMBG is comparable to that of the Sauda Grey Gneiss.

Figure 2.3. Field photographs of Sauda Grey Gneiss outcrops

Figure 2.4. Field photographs of various amphibolite outcrops

### Nesflaten Suite

The Nesflaten Suite comprises gneisses ranging from basalt to rhyolite in composition. Outcrops of gneiss with fine (<10cm) alternations of mafic and felsic compositions exist, as do mica-rich quartz-feldspar layers; some of these may have epiclastic origins. As well as abundant hornblende and

plagioclase, garnet and staurolite are recorded from one unit. Exposures of the belt in the north display networks of white granite/pegmatite intruding the gneiss complex; these are likely connected to a Sveconorwegian pluton.

Figure 2.5. Field photographs of the Grey Gneiss, Zinc Mine Banded Gneiss and Nesflaten Suite.

Figure 2.6. Field photographs of various outcrops of the Storlivatnet pluton

#### **Amphibolites**

Numerous mafic bodies that are metamorphosed to metabasites/amphibolites are found within the gneisses and granitoids; this suite is separated from the Grey Gneiss on rather subjective grounds, the separation is largely based on field-relations. Lithologies that are true amphibolites, or are more felsic but rich in amphibole and grade into more mafic lithologies, or are mafic enclaves within other lithologies, are grouped as the amphibolite suite. Undeformed dykes that have straight-

margins and intrude all other suites are not included in this suite. However, some dykes/sills crosscut the fabric in the grey gneiss but are weakly deformed themselves, and these are included. Undeformed to weakly deformed gabbroic bodies are common, these are commonly heterogeneous

Figure 2.7. Aggregates of polygonal amphibole surrounded by plagioclase-rich matrix, aggregates likely replaced larger phenocrysts of olivine and pyroxene. Plagiclase is heavily altered to sericite. (Amphibolites- Medium-grained layered amphibolite - SA7-50)

Figure 2.9. Subidioblastic amphibole grain with corona that contains fine-grained Fe-Ti oxide grians. Matrix is dominated by seritised feldspar. (*Amphibolites- Medium-grained layered amphibolite - SA7-50*)

Figure 2.11. Elongate poikiloblastic amphibole grains that are subparallel to the fabric. Matrix is composed of finer-grained quartz and altered biotite and feldspar.

bodies, ranging from coarse-grained plagioclase-porphyritic diorites to fine-grained massive gabbro, often with a network of narrow (<10cm) leucosome veins running through them. Southwest of the town of Sauda, there is a layered gabbro body. The rhythmic layering is nearly flat-lying, repeats every 10-15cm's and comprises retrogressed hornblende at the base, grading into plagioclase at the

top. The layered body is intruded by an undeformed 1-2m wide tonalitic dyke, and within the surrounding area is disaggregated by more granitic material. The tonalite comprises plagioclase, quartz and biotite, with retrogression to sericite, epidote and chlorite. It appears to be the same composition as the top of the rhythmic gabbro layers, thus, the tonalite is interpreted to be a

Figure 2.20. Large anhedral biotite and titanite grains forming a restitic clot. Pseudohexagonal apatite grains are visible in the mafic minerals. Coarse biotite grains are rimmed with finer biotite, epidote and titnaite grains.

(Sveconorwegian intrusion - Undeformed porphyritic biotite granite, SA3-01)

Figure 2.21. Deformed biotite grain surrounded by finer biotite grains (top right), altered and twinned plagioclase (left of centre), surrounded by perthitic feldspar, and quartz grain with undulose extinction (bottom right). *(Sveconorwegian intrusion - Undeformed porphyritic biotite granite, SA3-01)* 

Figure 2.22. Myrmeckite development (left of centre) on edge of K-feldpar, anhedral titanite grain (right of centre), and chlorite after biotite (top right). (Sveconorwegian intrusion - Undeformed porphyritic biotite granite, SA7-80)

comagmatic back-veining feature which occurred in a brittle environment. Deformed within the grey gneiss and porphyritic granitoids are numerous mafic enclaves. These comprise biotite and amphibole with minor plagioclase and quartz, and resemble the mafic units within supracrustal belts. The age of the amphibolites is generally unconstrained. The tonalitic dyke that intrudes the layered gabbro is ~1500 Ma in age (see Chapter 3), thus, this gabbro is part of the ~1500 Ma magmatic event, or potentially could be older.

#### Granitoids

Weak to moderately deformed coarse-grained porphyritic granodiorites occur as sheets within the Grey Gneiss complex, ranging from metres to tens of metres in width. These are conformable to the

fabric of the Grey Gneiss, and generally have graded boundaries into the Grey Gneiss lithologies. Undeformed bodies of porphyritic granite also occur; these have varying mafic content, grading from porphyritic biotite-hornblende granodiorites to porphyritic biotite granites, and probably represent zoned plutonic bodies. The distinction between ~1500 Ma plutonic bodies and those of Sveconorwegian age is unclear, as both deformed and undeformed examples of each exist. Bodies of leucogranite occur also, generally in association with porphyritic granites. Again the age of these is problematic, as both ~1500 Ma and ~1050 Ma examples have been dated (Slagstad et al. 2008).

#### 2.2.2 Structure

The Sauda Grey Gneiss Complex contains a structural fabric which has variable imprint across the region. The strongest deformation is recorded by proto-mylonitic banded units; phenocrysts within these are stretched but do not record an interpretable sense of shear. The majority of the outcrops record a sub-vertical L-fabric. Strain-shadow formation may have been strong during the main deformation phase, because undeformed outcrops occur adjacent to highly deformed outcrops. Within single lithologies, strain localisation into cm's and 10cm's scale is common. The boundaries between different lithologies are diffuse due to recrystallisation and the variable strain. The complex nature of the outcrops probably reflects multiple phases of intrusions, which in turn have intruded and deformed supracrustal units.

Figure 2.23. Map of the study area with lower-hemisphere stereonets showing planes and lineations (black spots), arrows define the transect that the structural data were obtained from for each plot.

The dominant strike trend is NW-SE (see Figure 2.23); although fold closures were not seen in the field, the main regional structure is that of tight to isoclinal folding with sub-vertical fold axis that trend NW-SE. Lineations dip to the southeast predominantly, suggesting stretching along the NW-SE fold-axis, and also that the fold-axis may be dipping to the southeast. A broad zone of strong shear that occurs to the southwest of Saudafjord (SHEARZONE in Figure 2.23) has a strike perpendicular (NE-SW) to the regional strike trend. Within both the ZMBG and Nesflaten Suite, a strong sub-vertical S-fabric is penetrative in a NNE-SSW direction, and phenocrysts are commonly stretched into augen.

The age and origin of deformation within the region is not constrained, but is generally considered to be Sveconorwegian (Bingen et al. 2005b). The complex nature of many outcrops is probably related to intrusion-related deformation during the main magmatic event (i.e. inferred to be Telemarkian ~1500 Ma). The regional NW-SE strike trend must be younger than the ~1500 Ma magmatic episode, because it effects all of the units except for the undeformed granite plutons; thus, this strike direction likely formed in relation to regional Sveconorwegian deformation and metamorphism (see next section), but this has yet to be demonstrated. The broad NW-SE strike direction is compatible with compression in a NE-SW direction, as would be expected with Sveconorwegian collision with an indentor from the SW. However, the Sveconorwegian collision may have been oblique (Park et al. 1991; Romer 1996; Stephens et al. 1996; Bingen et al. 2001), in which case the dominant strike trend may reflect strain partioning in a transpressional regime. The dominant strike direction in the Hardangervidda Sector is E-W (Sigmond 1998), suggesting there may be more complexity to the regional structures than determined and discussed here.

#### 2.2.3 Metamorphism (summary)

The petrography of orthogneisses from the Grey Gneiss, Zinc Mine Banded Gneiss and Nesflaten Suite, indicates widespread regional metamorphism that peaked at amphibolite-facies (see figures 2.7 to 2.22) No examples of retrogression from granulite-facies are observed, and also, no relic igneous pyroxenes or olivines are observed. In some lithologies actinolite and epidote are the peak-metamorphic minerals, indicating lower-amphibolite-facies has been reached; in other examples hornblende and garnet are preserved, suggesting middle-amphibolite-facies. Retrogression from hornblende to actinolite is observed, as is retrogression from biotite to chlorite. Alteration of feldspars to sericite and sausserite is widespread. Veins are commonly quartz dominated, but occassionaly calcite filled. Metamorphic amphibole and plagioclase commonly are fabric-forming, suggesting peak metamorphism was likely synchronous with regional deformation. Metamorphic aureoles relating to undeformed granitoids were not observed.

### 2.3 Conclusions

The basement in the Suldal Sector is dominated by orthogneisses that are assumed to be 1540-1480 Ma in age (Bingen et al. 2005b; Slagstad et al. 2008); based on their petrology, petrography and

intrusive-relations, they are interpreted as mid- to upper-crustal, hypabyssal and supracrustal igneous rocks, intercalated together during multiple periods of intrusive activity during evolution of a mature volcanic arc. This arc complex was intruded by composite granitoid plutons during the Sveconorwegian orogeny. Mafic intrusions are related to the main arc event, but also cross-cut interpreted Telemarkian structures, and occasionally cross-cut Sveconorwegian granitoids. Metamorphism and regional deformation likely occurred (but this is not yet demonstrated) during the main collisional phase of the Sveconorwegian orogeny, with the undeformed granitoids intruding during a later phase of the orogeny. Some structures probably also formed during the Telemarkian arc event, as multiple phases of intrusion would lead to complex cross-cutting relations. The regional peak-metamorphic grade reached was middle-amphibolite-facies; retrogression to lower-amphibolite and upper-greenschist facies is common. Partial melting is observed in many outcrops, attesting to relatively high-temperatures. Leucosomes are commonly sub-parallel to the fabric, suggesting this partial melting may have been facilitated by shear deformation. Such partial melting and synchronous regional deformation are observed in other midcrustal gneiss complexes, including those that formed during the same orogenic period (e.g. Muskoka domain of the Laurentian Grenville Province; Slagstad et al. 2005).

## A chemical abrasion LA-ICP-MS and ID-TIMS U-Pb study of Mesoproterozoic magmatism in the Suldal Sector; constraints on Telemarkian and Sveconorwegian crustal evolution

**Aim** - In this Chapter U-Pb zircon ages using LA-ICP-MS are presented for gneisses and granitoids from the Suldal Sector; TIMS analyses are presented for a selection of the dated rocks to compare the precision and accuracy of the methods. The applicability of a chemical abrasion zircon treatment is assessed for use with the LA-ICP-MS method.

### 3.1 Introduction

In U-Pb geochronology, the Isotope Dilution Thermal Ionisation Mass Spectrometry (ID-TIMS) method has long been recognised as producing the highest level of precision. Using an ion probe (Secondary Ion Mass Spectrometry – SIMS) however, can give much greater levels of resolution, as individual growth zones of minerals can be targeted with the ion beam. Although being the most precise, TIMS analyses are also the most costly; SIMS analyses are also costly, but less so than TIMS. The recent advances in Laser Ablation Inductively Coupled Mass Spectrometry (LA-ICP-MS) has lead to a vast increase in the number of U-Pb analyses being achieved globally, partly because laser ablation systems can be coupled to already existing ICP-MS machines. This latter method is less costly than TIMS and SIMS and produces a greater number of results per machine time. The spatial resolution capabilities using LA-ICP-MS are greater than using TIMS, since the beam can be aimed at specific growth zones, but is typically less resolute than SIMS due to a greater beam diameter. The precision of LA-ICP-MS in reported U-Pb ages is variable, but is much less than that of TIMS and typically similar to that of SIMS. Some users regard LA-ICP-MS as more of a reconnaissance tool, and is useful for guiding further work prior to more precise TIMS analyses; the method has seen its greatest U-Pb based use in detrital zircon studies, and is also commonly used in Precambrian studies where high-precision is not always necessary. However, the overall precision typically reached (~1%) is up to a factor of 10 worse than ID-TIMS. A goal in LA-ICP-MS U-Pb geochronology is to improve analytical protocols that achieve precision on U-Pb ages that more closely approach the precision of ID-TIMS, and that result in a high proportion of concordant analyses.

The chemical abrasion method (Mattinson 2005) is now routinely used in TIMS U-Pb zircon geochronology to produce concordant populations that will give a precise age. Variably discordant data are one factor that limits the overall precision of LA-ICP-MS geochronology; this study assesses the use of chemical abrasion for increasing the precision in this method.
# 3.2 Geological Framework

Samples were taken from the Suldal Sector, SW Norway (see Chapter 2). A range of lithologies with a variety of deformation states were sampled in order to help constrain tectonothermal events in the region. Previous U-Pb studies suggest that much of the exposed basement formed in the period from 1520 to 1480 Ma (Bingen et al. 2005b; Slagstad et al. 2008). However, many of the ages obtained are imprecise (>  $\pm 10$  Ma), meaning that a relative chronology of events within the region is difficult to establish. Sampled units included the Zinc Mine Banded Gneiss (Figure 3.1); concordant porphyritic lenses within this sequence are dated at 1497  $\pm$  12 and 1496  $\pm$ 12 Ma (Bingen et al. 2005b). The Nesflaten Suite is also targeted; this belt has not been previously dated, but conformable and surrounding gneiss gives an age of 1499  $\pm$  12 Ma (Bingen et al. 2005b). Within the Sauda Grey Gneiss Complex (Figure 3.1), amphibolite, granodioritic and granitic gneisses were sampled. Deformed and undeformed coarse-grained granitoids that were expected to give Sveconorwegian ages were also targeted; previously published ages exist for granitoids of 1065  $\pm$  75 and 1018  $\pm$  33 (Bingen et al. 2005b). Sample locations for previous U-Pb determinations are shown in figure 3.1.

## 3.3 Methodology

U-Pb geochronology was determined on zircons by laser ablation multi-collector inductively coupled plasma mass spectrometry (LA-MC-ICP-MS), with a subset of samples being dated also by isotope dilution thermal ionisation mass spectrometry (ID-TIMS); both at the NERC Isotope Geosciences Laboratory, Nottingham.

Zircons were separated from coarsely crushed whole-rock samples using the following techniques, disk-milling, sieving to remove the >300  $\mu$ m fraction, Wilfley water table seperation, heavy liquid separation, and finally Frantz magnetic separation. Zircons from the non-magnetic fraction were picked under alcohol; for LA-ICP-MS, zircons were mounted in 1 inch diameter epoxy resin mounts and polished to expose an equatorial section through the grains. A fraction of each sample was chemically abraded prior to mounting to remove portions of grains that have undergone lead loss (Mattinson 2005). For the chemical abrasion, a bulk zircon fraction from each sample was annealed in a muffle furnace at 850°C for 60 hours in a quartz beaker with a loose-fitting lid. The zircon crystals were washed in warm 4N HNO<sub>3</sub>, and rinsed in ultra-pure water to remove surface contamination. The annealed and cleaned bulk zircon fraction was then chemically abraded in ~200  $\mu$ l 29N HF and ~20  $\mu$ l 8N HNO<sub>3</sub> at 120°C for 12 hours. The abraded fraction was then washed several times in ultra-pure water, washed in warm 3N HCl for several hours on a hot plate, and then rinsed again in ultra-pure water and 8N HNO<sub>3</sub> before picking. A few analyses were conducted on zircons that were not annealed or abraded, and were mounted on double-sided tape on a glass slide.

Figure 3.1. A) Geological sketchmap of the main geological provinces in the Fennoscandian Shield. B) Sketchmap of SW Fennoscandia showing the division of lithotectonic domains. C) Sketchmap showing the sample localities and new and previously published ages. Ha = Hardangervidda Sector, Su = Suldal Sector, RVA = Rogaland Vest-Agder Sector, TIB = Transcandinavian Igneous Belt, MUSZ = Mandal-Ustaoset Shear Zone, KPSZ = Kristiansand-Porsgrunn Shear Zone, SSSZ = Saggrenda-Sokna Shear Zone, VSZ = Vardefjell Shear Zone,  $\emptyset BZ = \emptyset$ stfold Marstrand Boundary Zone, SFDZ = Sveconorwegian Frontal Deformation Zone, PZ = Protogine Zone (modified from Bingen et al. 2005b). Errors on ages are quoted at  $2\sigma$ . Grid co-ordinates are zone 32V UTM.

For LA-MC-ICP-MS, the procedures were similar to those outlined in Horstwood et al. (2003). The analyses used a Nu Plasma HR multi-collector inductively coupled plasma mass spectrometer (MC-ICP-MS), coupled to a 193 nm solid state (UP193SS, New Wave Research) Nd:YAG laser ablation system, and an in-house designed low volume 'zircon ablation cell' based on the design principles

of Bleiner & Gunther (2001). Helium gas was introduced to the ablation cell to transport the ablated sample material. Solutions were aspirated using a Nu Instruments DSN-100 de-solvating nebulizer using an ESI PFA-50 nebuliser.

The counting array involved measurement of <sup>238</sup>U, <sup>235</sup>U, <sup>205</sup>Pb/Tl, <sup>203</sup>Pb, and <sup>202</sup>Hg on Faraday cups, and <sup>207</sup>Pb, <sup>206</sup>Pb, and <sup>204</sup>Pb/Hg on discrete dynode ion-counting detectors. Tuning of the MC-ICP-MS at the start of each analytical session was achieved with the aspiration of a 500ppt solution of <sup>205</sup>Tl-<sup>235</sup>U. Ion counter to-Faraday gains were determined using a 100ppt <sup>205</sup>Tl-<sup>235</sup>U solution by jumping the <sup>205</sup>Tl peak through each ion counter and comparing the equivalent Faraday signal. During the ablation analyses a <sup>205</sup>Tl/<sup>235</sup>U solution was simultaneously aspirated, this allows for an improved correction of instrumental mass bias and plasma induced inter-element fractionation. The isobaric interference of <sup>204</sup>Hg on <sup>204</sup>Pb was corrected by simultaneous measurement of <sup>202</sup>Hg (assuming <sup>204/202</sup>Hg = 0.229887).

Large rasters are preferred to static spots, as these limit the amount of fractionation at the ablation site (Horstwood et al. 2003); however, the zircon fragments used in this study were relatively small and thus limited the size of raster. In 2008, the analyses were conducted with a  $20\mu m x 20\mu m$  raster using a 15µm spot at a rate of 15µm per second. 12 passes of the raster gave 40 seconds of analysis time, a washout of 30 seconds was allowed in between each analysis. The laser was set to 70% power at 5Hz, giving a fluence averaging 4.5 J/cm<sup>3</sup>. In 2009, a 25µm spot and a 25µm x 25µm raster made with a 15µm spot were used; again at 15µm per second, meaning 8 passes gave 40 seconds of analysis. Instead of a 30 second washout, the laser was warmed-up for 15 seconds prior to opening the shutter. 70-80% power and 5Hz were used, giving an average fluence of 2 J/cm<sup>3</sup>.

Primary standards used were Plešovice (Sláma et al. 2008) in 2008, and 91500 (Wiedenbeck et al. 1995) in 2009. These matrix-matched primary standards were analysed at regular intervals during each analytical session. The deviation of the average daily <sup>207</sup>Pb/<sup>206</sup>Pb and <sup>206</sup>Pb/<sup>238</sup>U values of the primary standard compared to the true value were used to normalize the sample data. The latter corrects for inter-element fractionation, whilst the former corrects for any drift or offset in the ion-counter gains recorded previously. To take account of the errors associated with the normalization process, the reproducibility of the primary standard ratios is propagated into the uncertainty of the sample ratios. A combination of GJ-1 (Jackson et al. 2004), 91500 or Plešovice were used as secondary standards to monitor the precision and accuracy of each analytical session.

Data were reduced and errors propagated using an in-house spreadsheet calculation package, with ages determined using Isoplot 3 (Ludwig 2003). Analyses that recorded <<0.01mV <sup>207</sup>Pb were rejected, and those that recorded a <sup>204</sup>Pb signal of >300 cps were assessed for possible common-Pb contributions and rejected where required.

The average reproducibility of the  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  and  ${}^{206}\text{Pb}/{}^{238}\text{U}$  ratios on the primary standards was 0.65 and 0.99% respectively for 91500, and 0.79 and 1.00% for Plešovice (1 $\sigma$ ). The average reproducibility of the secondary standards, after normalization to the primary standard, was 0.74 and 1.22% for  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  and  ${}^{206}\text{Pb}/{}^{238}\text{U}$  respectively on GJ-1, and 0.56 and 1.40% for Plešovice. The secondary standards gave  ${}^{206}\text{Pb}/{}^{238}\text{U}$  ages of 602.02 ± 13.08 Ma (2 $\sigma$ ) for GJ-1 (accepted  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  age 609 Ma, but its  ${}^{206}\text{Pb}/{}^{238}\text{U}$  age is accepted as ~602-604 Ma due to its slight normal discordance; Jackson et al. 2004), and 339.54 ± 12.99 Ma for Plešovice (accepted age 337.13 Ma; Sláma et al. 2008); and are thus accurate within 1.2% (2 $\sigma$ ) (see Figure 3.4).

Figure 3.2. U-Pb data on standards run during the LA-ICP-MS analytical sessions.

For ID-TIMS analyses, zircons were subject to a modified version of the chemical abrasion technique (see previous section). After this treatment, the zircons were sequentially washed in dilute high purity HCl, HNO<sub>3</sub> and water prior to dissolution. Zircon was dissolved in Parr vessels in 120  $\mu$ l of 29 M HF with a trace of 30% HNO<sub>3</sub> at 210 °C for 48 h, dried to fluorides, and then redissolved in 6 M HCl at 180 °C overnight. U and Pb were separated using an HCl-based anion-exchange chromatographic procedure (Krogh 1973). Pb and U were loaded together on a single Re filament in a silica-gel/phosphoric acid mixture (Gerstenberger & Haase 1997). TIMS analyses utilised the EARTHTIME <sup>205</sup>Pb-<sup>233</sup>U-<sup>235</sup>U (ET535) tracer solution. Measurements were performed on a Thermo Triton TIMS. Lead analyses were measured in dynamic mode on a MassCom SEM detector and corrected for 0.16 ± 0.04% / a.m.u. mass fractionation. Linearity and dead-time corrections on the SEM were monitored using repeated analyses of NBS 982, NBS 981 and U500. Uranium was measured in static Faraday mode on 10<sup>11</sup> ohm resistors or for signal intensities < 15 mV, in dynamic mode on the SEM detector. Uranium was run as the oxide and corrected for

isobaric interferences with an  ${}^{18}\text{O}/{}^{16}\text{O}$  composition of 0.00205 (determined through direct measurement at NIGL).

Loading blanks were <0.1 pg Pb and total procedural blanks were <1.5 pg Pb and <0.1 pg U, respectively. U-Pb dates and uncertainties were calculated using the algorithms of Schmitz and Schoene (2007) and a <sup>235</sup>U/<sup>205</sup>Pb ratio for ET535 of 100.21  $\pm$  0.1%. All common Pb in the analyses was attributed to blank and subtracted based on the isotopic composition and associated uncertainties analysed over time. The <sup>206</sup>Pb/<sup>238</sup>U ratios and dates were corrected for initial <sup>230</sup>Th disequilibrium using a Th/U<sub>[magma]</sub> of 4  $\pm$  1 applying the algorithms of Crowley et al. (2007). All analytical uncertainties are calculated at the 95% confidence interval; all sources of uncertainty include the systematic error from tracer calibration and <sup>238</sup>U decay constant.

## **3.4 Sample Descriptions**

## 3.4.1 SA3-02 tonalite dyke (Sauda Grey Gneiss Complex)

SA3-02 is an undeformed tonalitic dyke that intrudes a rhythmically layered metagabbro. The sample comprises strained quartz, coarse-grained heavily sericitised plagioclase feldspar, fine-grained biotite retrogressed to chlorite, and epidote. Zircon, titanite and Fe-Ti oxides occur as accessory phases. The dyke is 1-2m wide and has straight-sided margins. A network of at least two sets of veins cross-cuts the metagabbro; these are the same material as the dyke. Magma-mingling textures, including rounded margins to gabbroic enclaves in the tonalitic material, suggest a back-veining origin to some or all of the tonalite. In this scenario, the tonalite may have originated as a highly evolved differentiate of the gabbro that has intruded into the gabbro during cooling. The straight-sides to the dyke suggest it intruded in a brittle deformation regime.

#### 3.4.2 SA8-45 banded felsic gneiss (Nesflaten Suite)

SA8-45 is a sheared banded fine to medium-grained felsic gneiss. The sample comprises aligned biotite laths, recrystallised quartz and variably sericitised feldspar. Titanite and zircon occur as accessory phases. The gneiss is taken from the Nesflaten Suite that outcrops around the northern extent of Suldalsvatnet. In the area, basaltic to dacitic fine-grained banded gneisses dominate, and generally feature a strong vertical fabric with weak shearing.

## 3.4.3 SA7-04 rhyodacitic gneiss (Zinc Mine Banded Gneiss)

SA7-04 is a sheared fine-grained grey gneiss with scattered phenocrysts of sericitised feldspar and ribbons of quartz. Fine-grained biotite lathes are unaltered and aligned with the fabric. Zircon occurs as an accessory phase. The gneiss is taken from the Zinc Mine Banded Gneiss, 1km from the granite SA3-01. The banded gneiss in this area is variable, comprising narrow mafic schists, and

dominated by phyric and aphyric granodioritic to granitic banded gneisses. The gneisses are sheared, and feature a vertical fabric.

#### 3.4.4 SA7-86 metagabbro (Amphibolite)

SA7-86 is an amphibolite from a coarse-grained pegmatitic clot (~1m diameter) in a metagabbro body. The sample comprises feldspar heavily altered to sericite and sausserite, hornblende partially retrogressed to actinolite, biotite retrogressed to chlorite, and epidote. Abundant titanite, zircon and a Fe-Ti oxide occur as accessory phases. The metagabbro body is a ~2km wide body within the Sauda Grey gneiss on the west side of Saudafjord, parts of the metagabbro feature narrow felsic leucosomal veins. Within this 20km stretch of outcropping gneisses, a number of metagabbro bodies exist, including the layered gabbro mentioned above. Due to deformation and recrystallisation these bodies grade into the granodioritic gneisses so that the intrusive relationships cannot be determined. The sampled pegmatitic clot is free from deformation.

#### 3.4.5 SA7-58 biotite porphyritic granite (Sveconorwegian intrusion)

SA7-58 is a coarse-grained porphyritic granite comprising perthite and plagioclase, variably altered to sericite, strained quartz, and finer-grained strained biotite and titanite. Fe-Ti oxides, allanite, apatite and zircon occur as accessory phases. The granite is very weakly deformed, and intrudes and cross-cuts sheared basaltic-rhyolitic bimodal banded gneisses (including SA7-130). In this area (south of Suldalsvatnet), a variety of porphyritic granites intrude the supracrustals and gneissic basement; these are inferred to be of Sveconorwegian age.

### 3.4.6 SA7-130 banded rhyodacitic gneiss (Sauda Grey Gneiss Complex)

SA7-130 is a fine-grained felsic gneiss comprising fine-grained equigranular granoblastic quartz and feldspar, and biotite laths aligned with the fabric. Concentrations of biotite and Fe-Ti oxide grains occur in weakly developed bands. Zircon and titanite occur as accessory phases. The banded gneiss is highly sheared and occurs with subordinate amphibolite layers, protoliths to the gneisses may have been bimodal volcanic tuffs, and thus the area was originally mapped as supracrustals (Sigmond 1975). Undeformed porphyritic granite (including SA7-58) intrudes the gneisses.

#### 3.4.7 SA7-91 biotite granite (Sauda Grey Gneiss Complex)

SA7-91 is an undeformed porphyritic granite, comprising medium to coarse-grained perthitic feldspar that is variably altered to sericite, surrounded by a fine-grained granoblastic quartz matrix. Altered biotite, epidote and Fe-Ti oxides occur together in the matrix. Zircon occurs as an accessory phase. The granite is a >2km wide body on the southern side of Åkrafjord. Margins of the granite were not seen. To the north of the granite, gabbro-granodiorite-granite gneisses similar to those around Saudafjord occur. An undeformed 3m wide mafic dyke cuts through the granite outcrop.

Figure 3.3. Field photographs of sample localities for U-Pb dating, SGGC = Sauda Grey Gneiss Complex; ZMBG = Zinc Mine Banded Gneiss.

Figure 3.4. Field photographs of sample localities for U-Pb dating.

#### 3.4.8 SA3-60 banded rhyolitic gneiss (Sauda Grey Gneiss Complex)

SA3-60 is a felsic gneiss comprising equigranular fine-grained quartz and sericitised feldspar with a slight granoblastic texture, and small clots and schlieren of Fe-Ti oxides, altered biotite and titanite. Apatite and zircon occur as accessory phases. The felsic gneiss is highly sheared and isoclinally folded, and may have originated as a banded rhyolite. The felsic gneiss occurs as a 20m wide zone within a heterogeneous outcrop of fine to medium grained diorite to granodioritic gneisses.

## 3.4.9 SA3-04 granodiorite gneiss (Sauda Grey Gneiss Complex)

SA3-04 is a sheared granodiorite gneiss exhibiting an augen texture. The sample comprises strained quartz, heavily serictised and sausseritised feldspar, deformed into ribbons and augen, surrounded by fine-grained quartz, feldspar, biotite, epidote and titanite. Zircon and rare apatite occur as accessory phases. The augen gneiss outcrops on the periphery of a 5km wide zone dominated by a high sense of shear; zones of proto-mylonite have formed commonly in the centre of this zone. The protoliths in this region likely included high-level porphyries, and both phyric and aphyric tuffs. Rare highly stretched xenoliths of mafic material occur in the sampled outcrop.

#### 3.4.10 SA3-01 biotite-hornblende porphyritic granite (Sveconorwegian intrusion)

SA3-01 is an undeformed coarse-grained feldspar-phyric granite with abundant glomerocrysts of hornblende, biotite and titanite. Accessory phases include zircon and apatite. SA3-01 is from a large (>50km<sup>2</sup>) pluton that intrudes the zinc-mine supracrustals on its western edge. The sample is taken from adjacent to the zinc mine, 200m from the boundary with the Zinc Mine Banded Gneiss; at the boundary zone xenoliths of the supracrustals can be seen in the granite.

#### 3.4.11 SA8-69 porphyritic granodiorite (Sveconorwegian intrusion)

SA8-69 is a granodiorite containing seriate-textured phenocrysts of feldspar (typically mesoperthite), quartz, hornblende and biotite. Apatite, zircon and abundant titanite occur as accessory phases. Alteration of feldspar to sericite is abundant. The sample is from a heterogeneous

outcrop comprising diorite/granodiorite gneisses and porphyries; the granite is folded and weakly sheared with finer-grained gneisses and felsic veins.

# 3.5 Results

The ages quoted are based on mean  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  ages of mainly concordant points, as opposed to mean  ${}^{206}\text{Pb}/{}^{238}\text{U}$  or concordia ages;  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  ages ages are the most appropriate for material of this age, and for data with a degree of discordance. The errors on the mean ages derived from LA-ICP-MS data are calculated using two standard deviations of the mean, as this does not have the effect of reducing the uncertainty in large populations. All errors are quoted at  $2\sigma$  unless stated.

#### **3.5.1** SA3-02 tonalite dyke (Sauda Grey Gneiss Complex)

## LA-ICP-MS:

Nine chemically abraded grains and seven non-abraded grains were analysed. The nine abraded analyses are reversely discordant (-1.2 to -4.4%) and provide a weighted mean average  ${}^{207}$ Pb/ ${}^{206}$ Pb age of 1513 ± 5 Ma (MSWD = 0.52). The seven non-abraded analyses are concordant to slightly reversely discordant (0 to -2.1%) and provide a weighted mean average  ${}^{207}$ Pb/ ${}^{206}$ Pb age of 1521 ± 5 Ma (MSWD = 0.87). The two mean  ${}^{207}$ Pb/ ${}^{206}$ Pb ages are in error of each other, but have a slight offset. The weighted mean  ${}^{207}$ Pb/ ${}^{206}$ Pb age of all fifteen analysis is 1516 ± 14 Ma (MSWD = 1.03). *TIMS:* 

Four analyses on chemically abraded grains are slightly discordant (0.2 to 1.4%), and provide a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1511.1 ± 1.6 Ma (MSWD = 1.4; 95% conf.). Although reversely discordant, the chemically abraded grains analysed by LA-ICP-MS are closer in age to the TIMS analyses than the non-abraded grains.

## 3.5.2 SA8-45 banded felsic gneiss (Nesflaten Suite)

#### LA-ICP-MS:

Sixteen chemically abraded grains, and 8 non-abraded grains were analysed; both rasters and spots were used to compare each method. Of the spot analyses, 6 were chemically abraded grains and 6 were non-abraded grains. The chemically abraded grains were all reversely discordant, two of which to a large degree (-33.2 and -37.1%). The non-abraded grains were slightly reversely discordant (c. -2 to -6%), and two were normally discordant (+2.5 and +21.5%). The raster analyses have less discordance and less variation, being concordant to reversely discordant (0.2 to 12%), except for one grain that has normal discordance (5%) but is slightly older ( $^{207}$ Pb/ $^{206}$ Pb age of 1554 ± 14 Ma). Six grains were analysed by spots then rasters; 5 out of the 6 grains were more concordant when rasters were used. There is no offset in the mean  $^{207}$ Pb/ $^{206}$ Pb age between spots and rasters, both are 1519 Ma. A weighted mean  $^{207}$ Pb/ $^{206}$ Pb age using 18 analysis (including 2 rejected)

is given at  $1520 \pm 14$  Ma (MSWD = 1.06); this age is interpreted as the best estimate of crystallisation of the protolith to the gneiss.

## 3.5.3 SA7-04 rhyodacitic gneiss (Sauda Grey Gneiss Complex)

#### LA-ICP-MS:

Twentyone grains were analysed in total, 9 of these were rejected due to high common lead contents. 7 chemically abraded grains fall on concordia but with a spread of  $^{207}$ Pb/ $^{206}$ Pb ages from 1466 to 1531 Ma. 5 non-abraded grains are discordant (+3.2 to +27.2%), and give varying  $^{207}$ Pb/ $^{206}$ Pb ages; these are 1421 Ma (N=2), 1461 Ma, 1546 Ma, and 1620 Ma. The younger three grains when combined with the concordant grains fall on a regression line between 1493 ± 18 and 308 ± 160 Ma; if the 1535 Ma grain is included as well, then the regression gives an upper intercept of 1494 ± 25 Ma and a lower intercept of 176 ± 230 Ma. The 1620 Ma grain is interpreted to be an inherited grain; although the discordance of this analysis (16.4%) means that this age only gives an indication of the true age of the grain, it may be much older if non-zero Ma lead-loss events have affected the zircon. The spread in ages of concordant abraded grains may reflect a Proterozoic lead-loss event, or may reflect some inheritance of slightly older zircons with the true age being closer to 1470 Ma than the mean age, or may reflect a combination of both lead-loss and inheritance that cannot be distinguished with this dataset.

## TIMS:

Five analyses on abraded grains are discordant and fall on a regression line (MSWD = 8.8) that is similar to that given by the LA-ICP-MS analyses. The upper intercept of this regression at 1497  $\pm$  22 Ma overlaps the mean age of the concordant LA-ICP-MS analyses (1495 Ma). The lower intercept is imprecise (401  $\pm$  140 Ma) but may reflect a lead-loss event related to the Caledonian orogeny. The 1497 Ma age is interpreted to be the best estimate of the crystallisation age of the protolith of this gneiss.

## 3.5.4 SA7-86 metagabbro (Amphibolites)

#### LA-ICP-MS:

21 chemically abraded grains, 10 in the first analytical session, and 11 in the second were analysed. The 21 analyses provide a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1508 ± 10 Ma (MSWD = 0.36). All of the analyses are slightly discordant (+1.1 to +4.5). The second analytical session had lower precision on the  $^{206}$ Pb/ $^{238}$ U ratio than the first, and the mean  $^{207}$ Pb/ $^{206}$ Pb ages of the two sessions are slightly different; the first session gave 1506.0 ± 4.1 Ma (MSWD = 0.43) and the second gave 1512.9 ± 7.5 Ma (MSWD = 0.047). Despite the offset, all of the analyses are in error of each other. *TIMS:* 

Five chemically abraded grains are concordant to slightly normally discordant, and don't give overlapping  $^{207}$ Pb/ $^{206}$ Pb ages. The weighted mean of the two most concordant grains is 1497.6 ± 1.5 (MSWD = 3.2), and is interpreted as the best estimate of the crystallization age of the metagabbro.

Figure 3.5. Results from U-Pb dating for SA3-02 and SA8-45. All errors are  $2\sigma$ . all weighted mean ages are  ${}^{207}Pb/{}^{206}Pb$ . Dashed white squares are raster ablation sites, and circles are spot sites.

SA7-04 rhyodacitic gneiss (Zinc Mine Banded Gneiss)

Figure 3.6. Results from U-Pb dating for SA7-04 and SA7-86. All errors are  $2\sigma$ . all weighted mean ages are <sup>207</sup>Pb/<sup>206</sup>Pb. Dashed white squares are raster ablation sites, and circles are spot sites.

SA7-91 biotite granite (Sauda Grey Gneiss Complex)

Figure 3.7. Results from U-Pb dating for SA7-58, SA7-130 and SA7-91. All errors are  $2\sigma$ . all weighted mean ages are  ${}^{207}Pb/{}^{206}Pb$ . Dashed white squares are raster ablation sites, and circles are spot sites.

SA3-60 banded rhyolitic gneiss (Sauda Grey Gneiss Complex)

SA3-04 granodiorite gneiss (Sauda Grey Gneiss Complex)

SA3-01 biotite-hornblende porphyritic granite (Sveconorwegian intrusion)

Figure 3.5. Results from U-Pb dating for SA3-60, SA3-04 and SA3-01. All errors are  $2\sigma$ . all weighted mean ages are  ${}^{207}Pb/{}^{206}Pb$ . Dashed white squares are raster ablation sites, and circles are spot sites.

Figure 3.9. Results from U-Pb dating for SA8-69. All errors are  $2\sigma$ . all weighted mean ages are  ${}^{207}Pb/{}^{206}Pb$ . Dashed white squares are raster ablation sites, and circles are spot sites.

Other <sup>207</sup>Pb/<sup>206</sup>Pb ages are 1494, 1500 and 1507 Ma; the oldest two of these may represent some inheritance of slightly older material during intrusion and crystallisation of the gabbroic body. Although inheritance (and zircon crystallisation in general) is typically low in mafic rocks, examples are documented such as those found in a mid-ocean ridge setting (Schwartz et al. 2005). The 1498 Ma age is interpreted as the best estimate of crystallisation of the amphibolites.

#### 3.5.5 SA7-58 biotite porphyritic granite (Sveconorwegian intrusion)

#### LA-ICP-MS:

9 analyses on non-abraded grains give a weighted mean  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  age of  $1068 \pm 30$  Ma (MSWD = 1.19). The  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  ages have a slight spread, ranging from 1048 to 1084 M; and the data have variable discordance (-3 to 6.9%).

## TIMS:

4 chemically abraded grains give a weighted mean  ${}^{207}$ Pb/ ${}^{206}$ Pb age of 1047 ± 1 Ma (MSWD = 0.074); the analyses are concordant to slightly normally discordant. 6 of the LA-ICP-MS just overlap (±2 $\sigma$ ) with the TIMS analyses, whereas 3 grains are older and don't overlap. Given that a similar granitoid from the same region (SA8-69) has an older 1068 Ma age (see Section 3.5.11); the spread in ages in this granite may represent zircon growth during a prolonged crystallisation and/or

multiple-phase intrusion of this composite pluton. The 1047 Ma TIMS age is interpreted as the best estimate of the age of crystallisation of this granite however.

## 3.5.6 SA7-130 banded rhyodacitic gneiss (Sauda Grey Gneiss Complex)

### LA-ICP-MS:

9 analyses on chemically abraded grains are fairly concordant (-1.3 to +1.2%), and give a weighted mean  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  age of 1503 ± 11 (MSWD = 1.8; error calculated using a constant external error for each data point of 20)

## TIMS:

8 chemically abraded grains give a regression with an upper intercept at  $1511 \pm 3$  Ma and a lower intercept at  $806 \pm 34$  Ma (MSWD = 2.1). The 8 analyses are variably normally discordant. The TIMS upper intercept age is interpreted as the best estimate of crystallisation of the protolith. The lower intercept although not falling at an exact Sveconorwegian age, may represent lead-loss during this orogenic period.

## 3.5.7 SA7-91 biotite granite (Sauda Grey Gneiss Complex)

### LA-ICP-MS:

10 chemically abraded grains were analysed. The analyses are slightly discordant (-0.7 to +2.9%), and give a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1516 ± 15 Ma (MSWD = 0.64). *TIMS:* 

4 chemically abraded grains give a weighted mean  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  age of  $1503 \pm 1$  Ma (MSWD = 1.2). The analyses are concordant to slightly normally discordant. This TIMS age is interpreted as the best estimate of crystallisation of the granite.

## 3.5.8 SA3-60 banded rhyolitic gneiss (Sauda Grey Gneiss Complex)

## LA-ICP-MS:

10 chemically abraded grains, 7 in the first session, 3 in the second, and 4 non-abraded rim analyses were conducted. The chemically abraded analyses are fairly concordant (2.7 to -2.8% discordance), and give a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1518 ± 13 Ma (MSWD = 0.47). The four rim analyses have large uncertainties ( $^{206}$ Pb/ $^{238}$ U ± ~3 to 9% 2 $\sigma$ ) and are discordant (21.6 to 1%), but have  $^{207}$ Pb/ $^{206}$ Pb ages overlapping those of the abraded grains. The upper intercept age of these four grains at ~1521 Ma and a lower intercept at ~0 Ma, suggests a lack of Precambrian lead-loss events affecting the zircon grains.

## 3.5.9 SA3-04 granodiorite gneiss (Sauda Grey Gneiss Complex)

#### LA-ICP-MS:

Eleven chemically abraded grains were analysed, along with nine non-abraded grains for rim analyses using tape-mounting. The eleven abraded grains provide a concordia age of  $1509 \pm 4$  Ma,

with all but one grain being concordant; the weighted mean  ${}^{207}Pb/{}^{206}Pb$  age is 1509 ± 14 Ma (MSWD = 0.54) One of the rim analyses was rejected due to high common lead, the other eight are imprecise, and have a large degree of normal discordance, but point towards an upper intercept at ~1509 Ma, and a lower intercept at zero. The rim data suggest no lead-loss events are recorded in the zircon grains. The 1509 Ma  ${}^{207}Pb/{}^{206}Pb$  age is interpreted to represent crystallisation of the porphyry.

# 3.5.10 SA3-01 biotite-hornblende porphyritic granite (Sveconorwegian intrusion)

#### LA-ICP-MS:

18 analyses were done in two sessions, 11 in the first and 7 in the second. All of the analysis are concordant to slightly discordant (less than 5%), and were conducted on chemically abraded grains. A weighted mean average  ${}^{207}$ Pb/ ${}^{206}$ Pb age is given by all 18 analyses of 1039 ± 15 Ma (MSWD = 0.26). No obviously inherited grains are recorded. Zircons are all oscillatory zoned with some discordance between zones visible on many grains. Central and outer zones have been analysed, but with no difference in age recorded. The discordant zoning likely represents replenishment of the cooling magma in combination with movement of the magma mush, but within the timeframe of analytical uncertainty (<15 Ma). The 1039 Ma age is interpreted as recording the crystallisation age of the granite.

#### **3.5.11** SA8-69 deformed porphyritic granodiorite (Sveconorwegian intrusion)

#### LA-ICP-MS:

14 analyses were conducted on 14 grains, 7 chemically abraded grains and 6 non-abraded grains. 6 out of the 7 abraded grains are concordant to slightly reversely discordant (-7.9 to +2%), and give a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1064 ± 9 Ma (MSWD = 1.07). The rejected grain is discordant (+18.2%) and has a  $^{207}$ Pb/ $^{206}$ Pb age of 1339 Ma. 7 analyses on the 6 non-abraded grains are concordant to slightly normally discordant (-0.9 to +7.1%), and give a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1070 ± 14 Ma (MSWD = 3; 95% conf.). The grain with both a core and outer growth-zone analysed gave an older age for the outer growth-zone (1095 ± 17 Ma) compared to the core (1051 ± 27 Ma); these ages are just in error of each other and indicate that the outer growth zone does not represent a younger magmatic/metamorphic growth. The weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of all the analyses (except the 1339 Ma grain) is 1069.3 ± 8.7 Ma (MSWD = 2; 95% conf.); this age is calculated using a constant external error, and is interpreted to be the best estimate of crystallisation of the granitoid.

## 3.6 Discussion

#### 3.6.1 Chemical abrasion for laser ablation studies

High-precision and high-accuracy U-Pb geochronology can be achieved more effectively with zircon data that lack discordance due to lead-loss. The chemical abrasion method (Mattinson 2005) removes domains which have lost lead, thus, residual zircon that is dated is considered to contain U-Pb systematics that have remained in a closed-system. Chemical abrasion involves two main steps, annealing with high temperatures and abrasion with strong acid at moderate temperatures. Annealing is undergone at temperatures of 800-1100°C, with the aim of removing low to moderate lattice damage from natural alpha, alpha recoil and spontaneous fission processes (Mattinson 2005). The method of annealing prior to chemical abrasion limits leaching effects that have been observed in previous studies (e.g. Mattinson 1997). Chemical abrasion following annealing can be achieved with one step or multi-step partial dissolution. During multi-step partial dissolution where the temperature is raised during each subsequent analysis, the steps typically remove zones with decreasing U+Th contents (Mattinson 2005). Previous to the combined annealing and abrading method, most laboratories used the 'air abrasion' method (Krogh, 1982), which removed outer zones of zircons which are typically more discordant; this method doesn't penetrate cracks and fractures in zircon grains however. Identifying inheritance in zircon grains may become more straightforward using the chemical abrasion method, as the effects of lead-loss are reduced (Mattinson 2005).

For ion microprobe and laser-ablation methods, annealing of radiation damage is considered to remove heterogeneities related to U-Pb fractionation during alpha recoil, as well as radiation damage, thus providing a more homogeneous zircon grain that will feature smoother sputtering during ablation. (Romer 2003; Mattinson 2005). Most LA-ICP-MS U-Pb analyses are routinely conducted on grains that are untreated, except perhaps for a clean in weak acid. The method employed here used a single step chemical abrasion (120°C for 12 hours in Hf and minor HNO<sub>3</sub>). For most samples, especially the older Telemarkian gneisses, this provided what can be described as an 'overkill' method, given that on average less than 5 to 10% of the original material was salvageable after chemical abrasion. For the undeformed granitoids where larger prismatic zircons were abraded, slightly more material was available after abrasion.

The results show that this single-step overkill method was successful in producing single populations of concordant material. Most of the LA-ICP-MS analyses fall into relatively tight groups with overlapping error ellipses. Where analyses were conducted in two different sessions on the same sample (e.g. SA7-86 and SA3-01), the offset between analyses in the different sessions highlights how reproducible the individual sessions were. Several of the samples gave analyses which were reversely discordant (e.g. SA3-02, SA8-45 and SA8-69). Reverse discordance is primarily produced by analytical artifacts, and only extremely rarely by natural processes. Where analyses were conducted on both untreated and abraded grains, the abraded grains were more reversely discordant. Also, in an example where both raster and spot analyses were conducted

(SA8-45), the spots gave greater reverse discordance than the rasters. Reverse discordance is only affecting the abraded grains, and is enhanced when using static spot analyses; this effect is therefore interpreted to represent a matrix-matching issue.

Inter-element fractionation is a major factor impacting on laser ablation analyses, Horn et al. (2000) showed that this fractionation can be related to the ablation pit depth, and is inversely exponentially correlated with spot size. A number of methods have been employed to limit such fractionation, such as rastering over large areas to limit pit depth (Horstwood et al. 2003), soft-ablation where laser power is increased slowly throughout the analyses (Hirata 1997), and active-focusing where the laser focus is changed throughout the analyses (Hirata & Nesbitt 1995). The method employed within this study was to use rasters, however, the small zircon sizes, especially after chemical abrasion, meant that rasters still involved 6 to 10 passes over the same area.

If the inter-element fractionation during analyses of the standard is similar to that of the unknowns, then the impact on the overall analyses will be limited. This is why zircon standards are used to normalize zircon unknowns (i.e. matrix-matching). Studies have shown however that the use of zircon standards for non-zircon unknowns such as monazite and titanite, can provide precise and accurate analyses if methods such as rastering are employed to reduce inter-element fractionation (Horstwood et al. 2006; Storey et al. 2006). The abraded zircon grains analysed within this study exhibited fractures, cracks and features that suggested they were rather skeletal. These features do exist in the large fragments of standard zircons (e.g. 91500). Thus, the matrix-matching effect is reduced. During analyses, ablation of more skeletal grains would lead to a greater degree of inter-element fractionation is interpreted to be the cause of reverse discordance. The worst case of reverse discordance (SA8-45) was achieved using zircons that exhibit the greatest amount of cracks, providing further evidence for the matrix-matching issue described.

Reverse discordance due to inter-element fractionation should occur directly away from 0 Ma leadloss. Real lead-loss on the other hand may have not occurred at 0 Ma. Therefore, the intercept of discordant analyses (i.e.  $^{207}$ Pb/ $^{206}$ Pb age), may not reflect the true age of the grain (see Figure 3.10). A difference in  $^{207}$ Pb/ $^{206}$ Pb age of the average of the untreated versus abraded grains is visible in SA3-02 (1521 ± 12 versus 1513 ± 10 Ma), and in SA8-69 (1070 ± 14 versus 1064 ± 9 Ma), and may reflect this effect. The accuracy of the final age is affected by this analytical artifact, and therefore need to be limited as much as possible.

The accuracy of some of the LA-ICP-MS ages determined in this study can be analysed by comparing with the TIMS ages. In five out of the six samples, the difference between the LA-ICP-MS and TIMS ages is less than 1% (0.27 to 0.86%). This overlap in ages can be viewed

qualitatively by observing the TIMS error ellipses falling within the LA-ICP-MS error ellipses in figures 3.5 to 3.7. In one example the difference between the two ages is closer to 2%; however, in this example (SA7-58) the LA-ICP-MS age is derived from a large spread in <sup>207</sup>Pb/<sup>206</sup>Pb ages, with older ages possibly representing inheritance of older material. Again, the TIMS ellipses fall within the majority of the error ellipses of the LA-ICP-MS analyses. The variation between mean <sup>207</sup>Pb/<sup>206</sup>Pb ages derived from chemically abraded and untreated grains where analysed, is also less than 1% for each sample (SA3-02, S8-45, SA8-69). The combined LA-ICP-MS and ID-TIMS study clearly shows that LA-ICP-MS analyses are accurate and in good agreement with reference values for both standards and unknowns as determined by accompanying ID-TIMS data.

Figure 3.10. U-Pb concordia plot, showing example of how analytical induced reverse discordance may effect a zircon which has non-zero lead-loss. A grain which was formed at 3500 Ma and exhibited lead-loss at 1500 Ma should fall on a tie-line between these two ages, but reverse discordance away from 0 Ma may push the grain onto concordia giving a spurious and meaningless age.

The overall precision on the LA-ICP-MS ages is equal or better than most published Precambrian ages on similar rocks that have been observed during review of the literature in this thesis; also the populations of zircons exhibit much less scatter throughout a suite of metaigneous samples than any observed in recent literature. In future, perhaps a less radical chemical abrasion step would be advisable, as this would leave zircon fragments which were larger, allowing for larger rasters, as well as less skeletal fragments which would limit inter-element fractionation issues. Analyses of untreated grains are also useful to check what effect the chemical abrasion has had in relation to non-zero lead-loss and inheritance.

#### 3.6.2 1.5 Ga Telemarkian crustal growth

From previous work, the crust within the Suldal Sector formed during the 1520-1480 Ma Telemarkian period (Bingen et al. 2005b). Combining the previously published ages with those in this study, the time-span for magmatism within this region is 1489 to 1520 Ma without errors included; including  $2\sigma$  errors the minimum time span is 1492 to 1509 Ma, whereas the maximum time span is 1475 to 1534 Ma. If unpublished ages from the Suldal Sector are included of 1475 ± 8, 1484 ± 10, 1486 ± 4 and 1521 ± 6 Ma (Slagstad & Marker 2009, unpublished data), then the maximum age range is slightly increased; but overall the 1520-1480 Ma age span of Bingen et al. (2005b) is fairly appropriate. This 40 million year age span is appropriate for a continental crust-building long-lived mature volcanic arc or active continental margin. Within this time frame the crust likely underwent phases of compression and extension, as these may occur in cycles of~10 million years in an accretionary orogen (Collins 2002).

Figure 3.11. Compilation of published ages (grey squares) and those determined in this study (black squares) from the Suldal Sector. Published ages are Bingen et al. (2005b). Error bars are 2sigma. Dashed lines mark the 1520-1480 Ma Telemarkian time span.

The hitherto undated Nesflaten Suite has an age of  $1520 \pm 14$  Ma, suggesting it formed in the earlier part of the Telemarkian period. The sample from the Zinc Mine Banded Gneiss did not yield a precise age, but the estimate provided here of  $1497 \pm 22$  Ma overlaps the previous ages on concordant porphyritic layers ( $1497 \pm 12$  and  $1496 \pm 12$  Ma; Bingen et al. 2005b). The Sauda Grey Gneiss yielded ages of  $1518 \pm 13$ ,  $1511 \pm 3$ ,  $1509 \pm 14$  and  $1503 \pm 1$  Ma; all of these ages fall in the earlier part of the Telemarkian period. The overlap between the Zinc Mine Banded Gneiss, Nesflaten Suite and Sauda Grey Gneiss agrees with the interpretation that the supracrustal belts defined by the earlier mapping (Suldal-Åkrafjord and Grjotdokki-Nesflaten; Sigmond 1978), do not form separate belts that lie upon an older gneissic basement, but are all part of the same event (see Chapter 2). The age of the metagabbro (SA7-86) at  $1498 \pm 2$  Ma confirms that this member of the 'amphibolite' suite (see Chapter 2) is part of the Telemarkian event. The  $1511 \pm 2$  Ma age for an undeformed tonalite dyke that intrudes a layered metagabbro suggests the gabbroic body (another member of the amphibolite suite), is of Telemarkian age, and also fairly early on in the Telemarkian period.

Undeformed units are dated at  $1511 \pm 2$  (SA3-02) and  $1503 \pm 1$  Ma (SA7-91), whereas deformed units are both older and younger than these ages. This suggests that deformation was not penetrative, but instead was partitioned, with certain units escaping either both Telemarkian and Sveconorwegian fabric-forming deformation. This means that a relative chronology based on structural fabrics is potentially misleading; such chronologies have been used in the past to help define tectonothermal events, for example in the Idefjorden terrane various granitoids were grouped based on their state of deformation (Åhäll et al. 1990). The use of structural fabrics in this way is advised against, given that strain can be highly localized over a range of scales.

In-situ U-Pb geochronological methods are useful for indentifying inheritance in magmatic suites since large zircon populations can be dated, and older cores that represent inherited zircons that have been overgrown can be analysed. About 350 zircons have now been analysed from Telemarkian rocks in the Suldal Sector. In this large population only one grain is outside of the error of the Telemarkian age span, this grain is discordant (+16.4%) and has a <sup>207</sup>Pb/<sup>206</sup>Pb age of 1620 Ma. The lack of inheritance in Telemarkian rocks suggests limited amounts of older material were available for inheritance, or that the magmas were capable of dissolving any inherited zircon (see discussion in Chapter 5). Some inheritance of Telemarkian age material during the prolonged Telemarkian event is suggested by the data, for example in SA7-86 precise TIMS <sup>207</sup>Pb/<sup>206</sup>Pb ages spread from 1507 to 1495 Ma, with 1498  $\pm$  2 Ma being the interpreted age of crystallisation. Cathodoluminescence images of the zircons (Figures 3.5 to 3.9), show that each sample comprises a population of zircons that have similar characteristics, which is compatible with their interpreted igneous origin. The zircons are mostly elongate and oscillatory zoned, and lack any obvious inherited cores or discontinuities. Zircons from SA7-86 are unzoned to weakly zoned and are fragments of larger zircons (>300  $\mu$ m), which is compatible with their interpreted crystallisation in a mafic composition.

## 3.6.3 Sveconorwegian events

The Sveconorwegian orogeny (e.g. Gaál & Gorbatschev, 1987; Bingen et al. 2008a) involved continent-continent collision between Fennoscandia and another continent of unknown origin. Sveconorwegian events within SW Fennoscandia have been split into four distinct phases (Bingen et al. 2008c). The Arendal phase (1140-1080 Ma) involved collision between the Telemarkia and Idefjorden terranes, and the thrusting of the Bamble-Kongsberg terrane over Telemarkia (Bingen et al. 2008c). The Agder phase (1050-980 Ma) represents the main continent-continent collisional

phase, with the collision possibly being oblique (Bingen et al. 2008c). Crustal thickening and associated regional metamorphism is estimated at have peaked at 1035 Ma (Bingen et al. 2008c).

Within the Suldal sector, metamorphism has been dated by the Re-Os method on Cu-Mo mineral occurrences (Stein & Bingen 2002), with the Sæsvatn belt recording various stages of metamorphism and deformation: onset of greenschist facies metamorphism and deformation at 1047  $\pm$  2 Ma, peak ductile deformation at 1032  $\pm$  2 Ma, incipient extension/relaxation at 1025  $\pm$  2 Ma and full relaxation (and brittle deformation) at 1017  $\pm$  2 Ma (Stein & Bingen 2002). Monazite analyses in a ~1500 Ma gneiss to the south of the Suldal Sector give a younger age of 1005  $\pm$  7 Ma, interpreted to represent amphibolites-facies metamorphism (Bingen et al. 2008b). A titanite age of 1009  $\pm$  10 Ma from the 1035 Ma Rosskreppfjord granitoid (Andersen et al. 2002a) provides further evidence for metamorphism of this age. From analyses of all available geochronological data, Bingen et al. (2008b) define M1 as regional medium-pressure protracted metamorphism that peaked in granulite-facies, and occurred from 1035 to 970 Ma. M2 peaked at 930-920 Ma and is related to intrusion of the Rogaland Anorthosite Complex, but did not affect the Suldal Sector (Bingen et al. 2008b). The crust in the Suldal sector is inferred to be in a brittle regime by 970 Ma, with regional decompression occurring from 970 to 955 Ma (Bingen et al. 2008b).

Separate rim analyses were conducted on two deformed units (SA3-60, SA3-04); for each of these samples the discordant rim analyses point towards lead-loss at ~0 Ma, suggesting there is no observable imprint from the Sveconorwegian orogeny on the U-Pb systematics. Only one sample (SA7-130) has an imprecise lower intercept that is near the range of the Sveconorwegian orogeny (at 806  $\pm$  34 Ma). This sample is highly deformed and some parts of the outcrop feature leucosome formation, however, the fabric and leucosomes are cross-cut by SA7-58 dated at 1047  $\pm$  1 Ma; this suggests that the 806 Ma age is unrelated to the deformation or partial melting of the sample. Overall, the imprint of the Sveconorwegian orogeny recorded in the Telemarkian basement in this U-Pb dataset is non-existent to minimal.

Four main magmatic suites are defined in Telemarkia that occur within the main Sveconorwegian orogenic period. These are the Feda Suite (~1050 Ma), Fennefoss Suite (~1035 Ma), Hornblende-Biotite Granite Suite (~970-930 Ma) and the Rogaland AMC Suite (~930 Ma) (Schärer et al. 1996; Bingen & van Breemen 1998; Andersen et al. 2002a, 2007a). The Feda Suite may have been produced in an active margin setting that existed just prior to continent-continent collision (Slagstad et al. 2008; Bingen & van Breemen 1998), or may represent melting of previous arc-related crust as a result of crustal thickening (Bingen et al. 2008c). The HBG Suite is considered to be post-collisional and likely formed via fractional crystallisation of mafic lower crust (Vander Auwera et al. 2003; 2003; Bogaerts et al. 2003, 2006; Bingen et al. 2006). The Rogaland AMC Suite intruded

contemporaneously with the latter stages of the HBG Suite, and likely formed from an anhydrous mafic lower crust (e.g. Longhi et al. 1999; Bolle et al. 2003).

This study has shown that a composite pluton, named here the Storlivatnet pluton, has ages of 1069  $\pm$  9 Ma, 1047  $\pm$  1, 1039  $\pm$  15 Ma (this study) and 1021  $\pm$  8 Ma (MM26181; Slagstad & Marker 2009, unpublished). The oldest age (~1069 Ma) is from a strongly deformed porphyritic granitoid. The next youngest ages of 1047 and 1039 Ma are from relatively undeformed porphyritic granitoids (although some undulose extinction is observed). Thus, it can be inferred that deformation of the oldest granitoid occurred after 1069  $\pm$  9 and prior to 1047  $\pm$  1 Ma. It is not known whether the deformation of this granitoid is related to the NW-SE striking fabric-forming deformation that effects much of the older Telemarkian crust; but the data suggest at least some deformation occurred early on and perhaps slightly older than the Agder phase (1050-980 Ma) of the Sveconorwegian orogeny in the Suldal Sector.

The oldest Sveconorwegian granitoids dated hitherto, are the Mandal-Svindal Unit (1051 + 2/8 Ma), Veggja-Leland Unit (1051 + 2/8 Ma) and the Liland Unit (1051 + 2/4 Ma), all belonging to the Feda Suite (Bingen & van Breemen 1998). The  $1069 \pm 9$  Ma age for the Storlivatnet pluton pushes back the recorded onset of Sveconorwegian magmatism by some 18 million years. Bingen et al. (2008c) suggest that the Feda Suite may have formed by melting of older crust due to crustal thickening. Crustal thickening is inferred to have peaked at 1035 Ma (Bingen et al. 2008b); however, for crustal thickening to have produced all of the early-Sveconorwegian granitoids it must have occurred as early as ~1070 Ma, for which there is no direct evidence of. An alternative explanation is that the early-Sveconorwegian magmatism was related to subduction along a continental arc that was active just prior to continent-continent collision; such an explanation has already been postulated for the Feda Suite (Bingen et al. 1993; Bingen & van Breemen 1998; Slagstad et al. 2008). The deformation that occurred between 1069 and 1047 Ma (see above) is compatible with magmatism in an arc setting (at 1069 Ma) prior to collision and deformation in the Suldal Sector (at <1069 >1047 Ma), and followed by crustal thickening (at ~1035 Ma; Bingen et al. 2008b).

The only other event in the region of comparable age to the 1069 Ma Storlivatnet granitoid is that of deposition of the Kalhovde Formation in the adjacent Telemark Sector (Bingen et al. 2003). The age of deposition of this unit is interpreted to be  $<1065 \pm 11$  Ma based on an average of the six youngest detrital grains (Bingen et al. 2003); although, the youngest individual grains have  $^{207}$ Pb/ $^{206}$ Pb ages at  $1035 \pm 31$ ,  $1054 \pm 11$ ,  $1059 \pm 19$  and  $1061 \pm 11$ . This unit likely formed in an extensional setting, interpreted to have during regional thermal subsidence following 1.17-1.14 Ga volcanism (Bingen et al. 2003). This setting is at odds with a model whereby crustal thickening has produced the entire early-Sveconorwegian magmatic suite. Thus, a subduction-zone setting is preferred for the early stages of Sveconorwegian magmatism (Feda Suite). Brewer et al. (2002) advocate a continental

back-arc setting for 1.17-1.13 Ga volcano-sedimentary units within the Telemark Sector, suggesting that subduction-margin processes occurred until at least 1.16 Ga in the region. A subduction origin for the early-Feda magmatism suggests the subduction-margin was active until ~1050 Ma, just prior to continent-continent collision. Further evidence for a subduction-zone setting at ~1060 Ma is discussed in Chapter 8.

# 3.7 Conclusions

11 new ages are presented for gneisses/granitoids within the Suldal Sector, southwest Norway. Three ages from a composite pluton (Storlivatnet) that has both deformed and undeformed lithologies gave  $1039 \pm 15$ ,  $1047 \pm 1$  and  $1069 \pm 9$  Ma, and therefore these ages extend the age range of early-Sveconorwegian magmatism. Deformation of this pluton is inferred to have occurred between  $1069 \pm 9$  and  $1047 \pm 1$ . Calc-alkaline gneiss/granite/gabbro units that comprise the variably deformed basement in the region are Telemarkian in age, ranging from  $1497 \pm 22$  to  $1520 \pm 14$  Ma; within this crystalline basement, the Nesflaten and Zinc Mine Banded Gneiss 'supracrustal' belts formed contemporaneously with orthogneisses of the Sauda Grey Gneiss Complex. The influence of later orogenic events on the U-Pb systematics of the Telemarkian rocks is minimal. Pre-Telemarkian inheritance in Telemarkian rocks is almost non-existent (only one grain >1600 Ma is recorded).

Chemical abrasion is successful in producing relatively tight single-age populations of zircon fragments. However, chemical abrasion can cause matrix-matching issues such as inter-element fractionation; the use of large rasters is suggested for analyses, and fractured/skeletal grains should be avoided. Both the accuracy and precision of final ages using LA-ICP-MS and chemical abrasion are less than 1%, the ages determined are within 1% of the TIMS ages also. Slight offsets between different sessions and untreated versus abraded grains versus TIMS ages, suggests this method is limited to 1% precision on material of this age.

# The petrogenesis of 1.5 Ga magmatism in the Suldal Sector

Aim – In this chapter, whole-rock geochemical data from the ~1.5 Ga basement in the Suldal Sector are presented; the data are used to develop a model for the petrogenesis and tectonic setting of the main lithologies.

# 4.1 Introduction

The tectonic setting and petrogenesis of the crystalline basement rocks within the Telemarkia terrane is uncertain, primarily due to the scarcity in published geochemical data. Unpublished preliminary geochemical data on lithologies in the Suldal Sector suggest an active continental margin setting (Bingen et al. 2005b). Coeval volcanism in the Telemark Sector is bimodal with an A-type geochemical signature, and interpreted to have occurred in a continental 'within-plate' setting (Menuge & Brewer 1996), possibly in relation to extension in a 'behind-arc' convergent-margin setting (Slagstad et al. 2009). Abundant 1.52-1.48 Ga ages across the region suggest that the Telemarkia terrane was a location of substantial continental growth during this period (Bingen et al. 2005b; 2008a). The Gothian period (1.65-1.52 Ga) that occurred prior to the Telemarkian (1.52-1.48 Ga) period, built the Fennoscandian crust that is exposed to the east of Telemarkia, and is interpreted as an accretionary orogen with a single progressively maturing volcanic arc that is variably distal to Fennoscandia (Andersen et al. 2004a), or as several volcanic arcs accreted shortly after formation (Brewer et al. 1998; Åhäll & Connelly 2008). The Telemarkian crust may represent an extension of this accretionary orogen or may form an exotic microcontinent that was accreted during the Sveconorwegian orogeny (Åhäll & Connelly 2008; Bingen et al. 2005b).

# 4.2 Geological Framework

The Suldal Sector is an informal term for the central part of the west half of the Telemarkia terrane (Bingen et al. 2005b). It comprises a crystalline basement dominated by heterogeneous orthogneisses that are intruded by Sveconorwegian granitoids. Similar orthogneisses outcrop in the surrounding Hardangervidda, Rogaland and Telemark Sectors. The studied orthogneisses in the Suldal Sector have petrology, petrography and field-relations interpreted to represent mid- to supracrustal arc-related intrusions and volcanics (see Chapter 2). Gneisses sampled for geochemical analyses that are discussed in this chapter are taken from the region around the Sauda and Suldal communes (Figure 4.1). In the study area, the basement has been split up into the Sauda Grey Gneiss Complex, the Nesflaten Suite, the Zine Mine Banded Gneiss, Amphibolites and Granitoids (see Chapter 2), and are all 1.52-1.48 Ga in age (see Chapter 3).

# 4.3 Geochemistry

## 4.3.1 Analytical Techniques

Samples were analysed by XRF at the University of Leicester, UK, and by XRF and ICP-MS at the Geological Survey of Norway, Norway. The methods are outlined in the appendices. For XRF analyses at the University of Leicester, repeat analysis of certified reference materials gives a precision ( $2\sigma$ ) for major elements of <5% for SiO<sub>2</sub>, TiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, and MgO, <10% for MnO, CaO and Na<sub>2</sub>O, and 11% for K<sub>2</sub>O; precision on the trace elements is <10 % at contents over 15ppm.

## 4.3.2 Element Mobility

The rocks studied are orthogneisses that have been metamorphosed under amphibolite-facies and variably retrogressed in the greenschist facies, thus, their geochemistry has been liable to variable element enrichment and depletion. In this chapter, element concentrations of the rocks are used to determine their petrogenesis, the mobility of these elements should therefore be acknowledged.

Large-ion-lithophile-elements (LILE; e.g. Rb, Ba, K and Sr) are generally considered to be mobile, whereas high-field-strength elements (HFSE; e.g. Th, Nb, P, Ti, Hf, Zr, Y), rare-earth–elements (REE) and transition metals (e.g. Ni, V, Cr and Co) are considered to be immobile (Rollinson

1993). Most major elements form definable trends in Harker diagrams, although  $K_2O$  and  $Na_2O$  are relatively scattered (Figure 4.3); this is expected given the abundant alteration of feldspar to sericite (see Chapter 2). Other LILE such as Rb and Sr also define very scattered trends. Transition metals such as Co and V form well-defined trends, whereas HFSE such as Nb and Zr display scattered trends. This scatter may be caused by the samples not representing a single co-magmatic suite, but arising from multiple magmatic suites all with slightly different 'liquid lines of descent'; given that the samples span a period of >15 million years, this is considered to be highly probable. In evolved samples, the varying fractionation and accumulation of accessory phases which have high partition coefficients for Zr and Nb (such as zircon, titanite and rutile) will also cause scatter.

The ability to distinguish a distinctive suite (the tholeiitic amphibolites; see following sections), suggests limited mobility of elements. In summary, the geochemistry allows for a rough approximation of original protolith compositions; with discrimination based on HFSE rather than LILE favoured for petrogenetic interpretations.

#### 4.3.3 Sauda Grey Gneiss Association

The grey gneiss a calcic to calc-alkaline differentiation trend, is magnesian, metaluminous to weakly peraluminous, and sub-alkaline (see Figure 4.2). The samples range from quartz gabbro and diorite, through tonalite, to granodiorite and granite (QAP), and are not adakitic but fall in the field of normal arc rocks (Sr/Y vs Y; Figure 4.2). In Harker diagrams (Figure 4.3) the major elements display defined trends but with variable scatter. Al<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub> are roughly constant up to approximately 60% SiO<sub>2</sub> then decrease. CaO, MgO, MnO and Fe<sub>2</sub>O<sub>3</sub> display negative trends, with a visible inflection in MgO at 55% SiO<sub>2</sub>. P<sub>2</sub>O<sub>5</sub> defines a negative trend above 65 % SiO<sub>2</sub>, and a scattered slightly positive trend at lower SiO<sub>2</sub> content. Na<sub>2</sub>O defines a poor trend, but seems to display an increase up to 60% SiO<sub>2</sub>, then a constant trend. K<sub>2</sub>O defines a positive trend with significant scatter; an inflection at 69% marks an increase in K<sub>2</sub>O%.

The grey gneiss exhibits a variety of trends in trace elements relative to  $SiO_2$  (Figures 4.4 & 4.5). Rb and Ba both increase but exhibit considerable scatter, especially in Rb in evolved samples. Sr shows a negative correlation after ~65 % SiO<sub>2</sub>, but is widely scattered at lower SiO<sub>2</sub>. Ni, Cr, Co and V all show negative trends with silica enrichment (Cr and Ni not shown), but with some variation between them. V displays a rather consistent and well-defined trend from ~200ppm to 0ppm with a possible inflection to a shallower trend at 63% SiO<sub>2</sub>. Co displays a similar trend to that of V, decreasing from ~50ppm to 3ppm, again with an inflection at 63%. Both Nb and Zr show slightly increasing trends with SiO<sub>2</sub>, but there is considerable scatter. LREEs exhibit scattered trends especially in evolved samples, but show a general increase with silica enrichment. MREEs also show scattered positive trends. HREEs show scattered trends, but are fairly constant up to ~69% SiO<sub>2</sub>, then display a sudden increase in most of the evolved samples.

Figure 4.2. Geochemical classification of magmatic suites in the Suldal Sector. QAP = Quartz, Alkali-Feldspar, Plagioclase - IUGS classification, based on normative calculations; Y versus Sr/Y after Defant & Drummond (1990); FeO<sup>t</sup>/FeO<sup>t</sup>+MgO (Fe\*), Na<sub>2</sub>O+K<sub>2</sub>O-CaO (Modified Alkali Lime Index), ASI (Aluminium Saturation Index - molar Al<sub>2</sub>O<sub>3</sub>/CaO+Na<sub>2</sub>O+K<sub>2</sub>O) after Frost et al. (2001). Sub-alkaline/ alkaline field (Na<sub>2</sub>O+K<sub>2</sub>O) after Irvine & Baragar (1971).

In Primitive Mantle normalised spider diagrams (Figure 4.6) all lithologies show enrichment in all elements relative to Primitive Mantle. The greatest enrichment is that of the LILE, with Rb contents 30 to 300 times greater than Primitive Mantle. Strong depletion relative to other elements is seen in Nb, Ta, Sr, P and Ti. The depletion in Nb and Ta is recorded in basaltic compositions, and is

relatively constant with increasing silica enrichment. Sr, P and Ti are only slightly depleted in the basaltic samples, but exhibit a much greater degree of depletion with increasing silica enrichment.

Figure 4.3. Major element oxides versus  $SiO_2$  for magmatic suites in the Suldal Sector. Symbols as in figure 4.2.

In chondrite normalised REE spider diagrams (Figure 4.7), all lithologies show LREE enrichment relative to MREE, LREE enrichment relative to HREE, and only slight MREE enrichment relative to HREE. The amount of LREE to MREE enrichment is relative constant up to 60% SiO<sub>2</sub>, then

Figure 4.4. Selected trace elements versus SiO<sub>2</sub> for magmatic suites in the Suldal Sector. Symbols as in figure 4.2.

increases in more evolved samples. LREE to HREE enrichment is fairly constant throughout the suite, but exhibits large scatter in samples between >68% SiO<sub>2</sub>. MREE to HREE enrichment slightly decreases with silica enrichment. Total REE contents show a positive but scattered trend. In basaltic samples both small negative and positive Eu anomalies are exhibited, with increasing silica

Figure 4.5. Selected trace and REE elements versus SiO<sub>2</sub> for magmatic suites in the Suldal Sector. Eu\* = Eu/( $\sqrt{\text{Sm}^*}\sqrt{\text{Gd}}$ ). Symbols as in figure 4.2.

Figure 4.6. Primitive mantle normalised (Sun & McDonough 1989) spider-diagrams.

Figure 4.7. Chondrite normalised (Sun & McDonough 1989) spider-diagrams.

samples display less enriched profiles, two of which have positive Eu anomalies; these samples likely represent residual melts or cumulates with cumulative feldspar.

## 4.3.4 Zinc Mine Banded Gneiss

The Zinc Mine Banded Gneiss is a succession of calc-alkaline, metaluminous to weakly peraluminous and magnesian orthogneisses. The sample selection is bimodal in terms of silica content although intermediate compositions were observed in the field; differentiation trends are therefore not well-defined. Both the mafic and felsic populations show considerable scatter, but broadly correlate with trends shown by the Grey Gneiss. The REE were not measured on the ZMBG, but La and Y contents are similar to that of the Grey Gneiss, suggesting similar LREE to HREE fractionation and enrichment levels.

#### 4.3.5 Amphibolites

As discussed in Chapter 2, the amphibolites are not amphibolites *senso stricto*, but are a suite largely comprising amphbolites *senso stricto*, but also comprising amphibole-rich intermediate to felsic lithologies which are spatially related to amphibolite units. The amphibolites are calc-alkaline to alkali-calcic, ferroan, metaluminous and sub-alkaline (Figure 4.2). The suite displays a differentiation trend on the Harker diagrams that is well-defined above ~53% SiO<sub>2</sub>; at lower SiO<sub>2</sub> the trend is near vertical such that the samples appear to be scattered in some elements. In MgO, Co and V, the amphibolites have a well-defined negative trend throughout, in other elements (P<sub>2</sub>O<sub>5</sub>, Al<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub>, Sr) the amphibolites increase steeply to ~53% SiO<sub>2</sub> then have a shallow negative trend, and in some elements (REE, Nb, Zr) the amphibolites increase steeply at first then increase more gradually after ~53% SiO<sub>2</sub>. Some of the most primitive samples of the amphibolites suite (high MgO, and low SiO2), exhibit positive Eu anomalies and are less-enriched in REE (see Figure 4.7); these samples likely represent magmas that are cumulative in feldspar.

Above ~53% SiO<sub>2</sub> the trends displayed by the amphibolites are generally sub-parallel to the Sauda Grey Gneiss trends, except that depletion or enrichment relative to the Grey Gneiss is evident in most major and trace elements. In the major elements the amphibolites have higher TiO<sub>2</sub>, Na<sub>2</sub>O,  $P_2O_5$  and Fe<sub>2</sub>O<sub>3</sub>, lower Al<sub>2</sub>O<sub>3</sub> and CaO, and similar K<sub>2</sub>O contents. In the trace elements the amphibolites have higher Nb, Y, Zr, and V, and similar Rb and Ba; Co is higher in the most mafic amphibolites, but then drops off to a lower trend than that of the Grey Gneiss; Sr displays similar behavior to Al<sub>2</sub>O<sub>3</sub> and is low at the mafic end-member, but then has similar contents to that of the Grey Gneiss; and Al/Ga, which can be used to indicate feldspar fractionation is lower in the amphibolites. At similar SiO<sub>2</sub>, the REE display greater enrichment in the amphibolites relative to the Grey Gneiss (see Figure 4.5), although the LREE/MREE, LREE/HREE and MREE/HREE are similar between the two suites. In the Primitive Mantle normalized plot (Figure 4.7) the amphibolites exhibit similar depletions to those displayed by the Grey Gneiss. In summary, the
amphibolites have similar LILE (except for Sr), greater contents of incompatible elements, and higher Fe/Mg than the Grey Gneiss.

#### 4.3.6 Granitoids

The granitoids are porphyritic, granodioritic to granitic, calc-alkaline, metaluminous to weakly peraluminous and sub-alkaline (Figure 4.2). The majority of the samples plot in the ferroan field (Fe\*), however, this does not mean they have evolved from less-differentiated ferroan magmas, since at high silica content most magmas become enriched in Fe\* (Frost et al. 2001). The granitoids have similar major and trace element contents to those in the Sauda Grey Gneiss (Figures 4.3 to 4.6). In Primitive Mantle normalized diagram (Figure 4.7) the granitoids display similar enrichment and depletions to those of the most evolved members of the Grey Gneiss Suite.

## 4.4 Petrogenesis

The Zinc Mine Banded Gneiss and granitoids were only studied at a reconnaissance level, thus their petrogeneses is not discussed separately. These suites have petrographic and petrologic similarities to the Sauda Grey Gneiss and are of the same age; therefore they are assumed to have a similar petrogenetic origin.

#### 4.4.1 Grey Gneiss

The LILE enrichment and depletion in Nb, Ta, P and Ti are all characteristic of magmas produced in a supra-subduction zone setting. LILE enrichment (Rb, Ba, K) is generally attributed to addition of these elements from subduction zone fluids (e.g. Saunders et al. 1991). Depletion in Nb and Ta has been related to both retention of phases that accommodate these elements in the downgoing slab and to the immobility of these elements relative to LILE (e.g. Saunders et al. 1980; Green et al. 1981; McCulloch & Gamble 1991; Kelemen et al. 1993; Brenan et al. 1994). The fact that the basaltic compositions exhibit Nb and Ta depletion is compatible with a pre- crustal-differentiation origin for this depletion. Ti and P exhibit greater depletion with increasing SiO<sub>2</sub>, therefore they are related to processes occurring during differentiation. Ti is likely depleted by fractionation of Fe-Ti oxides and titanite, and P is depleted by fractionation of apatite. The HFSE enrichment in the Grey Gneiss is typical of continental arc magmas. This enrichment, which is not typically observed in intra-oceanic arcs, is often related to an enriched source, e.g. asthenospheric mantle as opposed to depleted mantle, and/or to crustal contamination (i.e. the 'within-plate' component; Pearce 1983).

Evolved compositions have various origins in arc magmatic suites. Simplistically these involve fractional crystallisation with or without assimilation (e.g. Bowen 1928; Reagan et al. 2003; Kuritani et al. 2005; Greene et al. 2006), or partial melting of already crystallised crust (e.g. Tamura & Tatsumi 2002; Smith et al., 2003; Vogel et al. 2006). In reality both of these mechanisms likely occur together; in oceanic arcs where older silicic crust may not exist, the emplacement of mafic

sills, remelting of previous sills, fractionation of both mafic sills and partial melts, and mixing between different compositions, can lead to a crustal section with a range of compositions typical of volcanic arcs (i.e. a deep hot crustal zone; Annen et al. 2006).

Straight-lines on differentiation trends are indicative of magma mixing. Within the Grey Gneiss, straight-lines in Harker diagrams are exhibited in some elements, but the existence of inflections in many elements suggests fractional crystallisation played a significant role in differentiation. The sudden increase in REE, Zr, Y and K at ~69% SiO<sub>2</sub> means that intermediate compositions do not fall on a mixing array between felsic and mafic end-members, excluding a mixing-hypothesis for intermediate compositions. Inflections occur at lower SiO<sub>2</sub> also, for example MgO at ~55-60% SiO<sub>2</sub> and Na<sub>2</sub>O and Al<sub>2</sub>O<sub>3</sub> at ~60-65% SiO<sub>2</sub> and in trace elements at ~63% SiO<sub>2</sub> (Ga) and ~60-65% (Sr, Co). Thus, basaltic andesite compositions do not correspond to mixtures between basaltic and andesitic members, excluding a mixing-process at low silica enrichment. At 50 % SiO<sub>2</sub>, Ni does not fall on a trend but is widely scattered, suggesting variable olivine content in the basaltic endmembers. The evidence noted above points towards fractional crystallisation from mafic endmembers, as opposed to mixing between mafic and silicic end-members, for the main process of differentiation within the suite. However, this does not exclude a partial melting process for differentiation. The discrimination between partial melting and fractional crystallisation can be achieved using the changes in REE abundance with magma differentiation (Brophy 2008). In the Grey Gneiss, the slightly increasing LREE, and constant HREE at intermediate compositions are most compatible with fractionation of basalt in the lower crust with amphibole present, and the enrichment in all REE at high silica content is compatible with mid-to upper-crustal fractionation of basalt where amphibole is not present (Brophy 2008).

High-silica melts generally contain crystallising phases that have high partition coefficients for LREE, MREE, and HREE (e.g. zircon, allanite, apatite, monazite). Within the Grey Gneiss suite, a sudden increase is seen in MREE and HREE at ~69% SiO<sub>2</sub>. If this point marks the onset of crystallisation of certain accessory phases, then the sampled orthogneisses must contain accumulations of these phases, as opposed to originating as residual liquids. Apatite is found in most samples with SiO<sub>2</sub> greater than 60%, thus, it is not expected to cause the change at ~69%. Monazite is not recorded in any of the samples and is thus assumed not to be a fractionating phase. Zircon has  $D_{LREE} < D_{MREE} < D_{HREE}$  and allanite has  $D_{LREE} > D_{MREE} > D_{HREE}$ , thus, zircon is the most likely candidate for controlling the observed REE changes. An increase in Zr at ~69 % corresponds to the MREE and HREE increase, supporting the hypothesis that this phase is responsible for the change in REE concentrations. However, samples with low HREE samples do not have corresponding low Zr values, invalidating this hypothesis. Another phase that accommodates both Zr and REE is amphibole. The termination of amphibole as a fractionating phase would produce an increase in

REE and Zr, as these would no longer be removed from the melt. As  $D_Y$  in amphibole is greater than 1, the constant Y abundances and then sudden increase at ~69% support this notion. Thus, in agreement with the trends modelled by Brophy (2008), it is suggested that the change in REE concentrations in the Grey Gneiss suite is strongly controlled by amphibole fractionation.

Along with amphibole, the role of other fractionating minerals can be assessed using major and trace element changes with differentiation. The increase in the size of the negative Eu anomaly with differentiation indicates plagioclase was fractionating throughout the entire differentiation process. The inflection in the  $Al_2O_3$  and Sr trends indicate that plagioclase had a greater control on differentiation after ~60 % SiO<sub>2</sub>. Decreases in CaO, MgO, and Fe<sub>2</sub>O<sub>3</sub>, and increases in Na<sub>2</sub>O and K<sub>2</sub>O with differentiation, are compatible with fractionation of clinopyroxene. Decreases in transition metals (Ni, Co, V), MgO and Fe<sub>2</sub>O<sub>3</sub> are compatible with fractionation of Fe-Ti oxides. In summary, the trends displayed are typical of POAM - Plagioclase, olivine (and/or orthopyroxene), clinopyroxene (and/or amphibole) and magnetite fractionation; such fractionation is typical in arc suites for the formation of andesitic compositions from mafic parent melts (Gill 1981).

To assess whether the crystallizing phases determined above are compatible with the REE trends, a simple fractional crystallisation model was tested (Figure 4.8; Table 4.1). There are inherent problems with modelling of trace elements (see Rollinson 1993); particularly of concern are the partition coefficients used, as these are dependent on factors which are often not controlled in the modelling, i.e. temperature, oxygen fugacity, pressure, and  $H_2O$  activity. Partition coefficients also vary as the melt evolves. However, modelling can still provide a useful indication of what assemblages are compatible with the observed trends. REE concentrations were modelled in two stages using Rayleigh fractional crystallisation; these stages comprise the fractionation of an average mafic Grey Gneiss composition to produce an andesitic composition, and the fractionation of an average andesitic composition to produce a dacitic composition. At higher silica contents trace elements become highly dependent on accessory phases such as zircon, thus, rhyolitic compositions were not modelled. In the first stage, a best fit is achieved with 30-40% fractionation of an assemblage comprising plagioclase, clinopyroxene, hornblende and magnetite. In the second stage, a best fit is achieved by 30-40% fractionation of an assemblage similar to that in stage 1, but with greater plagioclase content and the addition of minor apatite content. These assemblages are similar to those modelled in other Precambrian continental arcs (Slagstad et al. 2004).

In summary the major, trace and REE trends within the Grey Gneiss suite suggest that it formed by fractional crystallisation of a basaltic parent melt, with multiple stages of fractionation probably occurring at different levels in the crust. This scenario is compatible with a deep hot crustal zone setting (Annen et al. 2006). The geochemistry of the studied suites suggests formation in a volcanic

arc setting. The range and abundance of evolved compositions is suggestive of a mature island arc or continental arc; this inferred tectonic setting for the Grey Gneiss suite is here named the Suldal arc.

Figure 4.8. Rayleigh fractional crystallisation modelling of REE contents in the Sauda Grey Gneiss. Basalt, Andesite and Dacite are average REE contents of the Grey Gneiss from 45-55%, 55-63% and 63-67% SiO<sub>2</sub> respectively. Modelled melts are shown at 20% increments. Results and partition coefficients are shown in table 4.1.

#### 4.4.2 Amphibolites

The amphibolites, although displaying similar trends to the Grey Gneiss Suite, exhibit features that are typical of 'A-type' rocks, i.e. low CaO, high Fe/Mg and Ga/Al, and enrichment in incompatible elements (Whalen et al. 1987; Collins 1982). A-type magmas are typical of post-collisional and extensional tectonic settings, but are not typical of the main arc-forming stage in subduction-zone settings (Bonin 2007). In the Suldal Sector, at least some of the amphibolites crystallised during the ~1500 Ma event (see Chapter 3). Thus, formation of the amphibolites for at least some of the samples must have occurred contemporaneously with formation of the Grey Gneiss suite. Different mafic bodies within the study area have different structural fabrics recorded in them, with some being undeformed dyke-like intrusions; this suggests that emplacement of these magmas may have occurred on multiple occasions since the ~1500 Ma event. The gabbro bodies that are inferred to be ~1500 Ma are typically less deformed than the Grey Gneiss they intrude, suggesting the amphibolites may have intruded in a later stage of arc development than the bulk of the Grey Gneiss, however, one sample of amphibolite is an enclave from within highly deformed Grey

Gneiss, suggesting earlier or concomitant formation. Also, two samples from a zone of magma mingling ('hybrid' in figures 4.2 to 4.5), have major and trace element contents that straddle the magnesian Grey Gneiss and ferroan amphibolite trends, suggesting some mingling has occurred between these magma series upon intrusion. The A-type amphibolite suite is interpreted to have evolved contemporaneously with the Grey Gneiss suite, thus, the cause of the compositional difference between the two suites is likely related to changes during magma differentiation, changes in source conditions, and/or changes in the source material.

As previously discussed, fractionating phases in the Grey Gneiss suite likely included plagioclase, olivine, pyroxene, amphibole, olivine and Fe-Ti oxides. The amphibolites have higher Ga and lower CaO and  $Al_2O_3$ , this can be explained by leaving a plagioclase residue in the parent melt. The lower MgO in the amphibolites, suggests a greater olivine residue. V is higher in the more mafic end of the amphibolite suite, but has a sharp decrease so that intermediate compositions have lower V than the Grey Gneiss. TiO<sub>2</sub> is also initially much higher in the amphibolites. The trends in Ti and V suggest that residual Fe-Ti oxides were less important in the parent melt of the amphibolites, but probably formed part of the fractionating assemblage later on in the differentiation. The compositional differences discussed so far can be related to an increase in residual plagioclase and olivine in the amphibolites, and an increase in residual Fe-Ti oxides in the Grey Gneiss suite.

The amphibolites also show an increase in the HFSE, MREE and HREE (i.e. the incompatible elements), whereas the LILE are similar between the two suites. Increases in incompatible elements can be related to either smaller degrees of partial melting, or partial melting of a mantle source that is less depleted by previous melt extraction (enriched mantle). Isotope data can often aid the discrimination between these processes. Hafnium in zircon data on two amphibolite samples (SA7-86, ROG525; chapter 5) suggest that the source was similar in terms of crustal versus mantle contribution. 'Enriched mantle' sources, which in arc/back-arc settings are generally related to asthenospheric mantle input, typically lack a negative Nb anomaly. The amphibolites have a negative Nb anomaly similar to that of the Grey Gneiss, suggesting a similar mantle source, or at least that the mantle sources underwent the same modification by subduction-zone fluids. The geochemical data thus suggest that two processes are responsible for the development of the two suites, the fractionating assemblage, and the degrees of partial melting.

The amphibolite suite is likely produced by fractionation of a parent magma with residual plagioclase and olivine ( $\pm$  clinopyroxene/hornblende), whereas the Grey Gneiss includes Fe-Ti oxide as a residual phase. Differences in the stability of crystallizing phases during magma differentiation depend on a number of intensive parameters, namely temperature, pressure, oxygen fugacity and water activity. Experimental studies have demonstrated the significance of water

content in primary basaltic magmas, in particular an increase in the water content leads to the early appearance of Fe-Ti oxides and the suppression of plagioclase crystallization (Gaetani et al. 1993; Sisson & Grove 1993; Kawamoto 1996). An increase in pressure leads to the reversal of this, with earlier plagioclase crystallisation and a greater proportion of plagioclase relative to Fe-Mg silicates (Grove et al. 2003). Oxygen fugacity generally correlates with water activity, with reducing conditions normally being relatively anhydrous and oxidizing conditions being hydrous. The effect of oxygen fugacity has similar effects to that of water, although water has a much greater effect than oxygen fugacity or pressure (Hamada & Fuji 2008). Oxygen fugacity controls the stability of Fe-Ti oxides (Feig et al. 2006; Botcharnikov et al. 2008), with magnetite crystallizing first in conditions above fayalite-magnetite-quartz (FMQ), and ilmenite appearing first in conditions below FMQ (Toplis & Carroll 1995).

The relative amount of Fe-Ti oxide to plagioclase crystallisation has a strong control on magma differentiation. If Fe-Ti oxides crystallize early, then the magma will become increasingly enriched in silica, and enrichment in iron will be suppressed; thus, the melts will follow a calc-alkaline trend. If Fe-Ti oxides do not crystallize early on, then the melt will become progressively enriched in iron, and form a tholeiitic trend. This leads to the general inference that calc-alkaline magma suites are relatively hydrous and oxidizing, and tholeiitic magma suites are anhydrous and reducing (Sisson & Grove 1993; Baker et al. 1994).

Tholeiitic (ferroan) magmas are typical of oceanic island arcs, where the crust is relatively thin, however, there are examples where they occur in the same volcanic arc as calc-alkaline (magnesian) magmas, for example in the Cascades (Baker et al. 1994), the Aleutians (Kay et al. 1982) and in Japan (Hunter 1988; Sakuyama 1981). The formation of tholeiitic and calc-alkaline trends in the same volcanic system has been explained by the difference in intensive parameters, for example Baker et al. (1984) advocate a deep source control on magma trends whereby the water content in the mantle varies, causing differences in fractionating assemblages in the parent magmas. At Aso volcano, SW Japan, a shallow level control is advocated for differentiation of tholeiitic and calcalkaline trends (Hunter 1998); whereby predominantly tholeiitic magmas evolve to calc-alkaline magmas with a change in the fractionating assemblage, but also with a decrease in crustal contamination. This is contrary to the general belief that calc-alkaline magmas involve greater amounts of crustal contamination (e.g. Grove & Baker 1984; Myers et al. 1984; Fujinawa 1988; Hora et al. 2009). Hora et al. (2009) advocate a shallow-level control on differentiation of tholeiitic to calc-alkaline suites, but where tholeiitic magmas evolve to calc-alkaline magmas via assimilation of crust/melts. In this model, tholeiitic series are 'clean' and characterized by rapid magma throughput and minimal crustal contamination, whereas calc-alkaline magmas are 'dirty', involving compartmentalized, stagnant assimilation-prone magma differentiation (Hora et al. 2009).

From the examples listed above, it would seem that the petrogenesis of the amphibolites evolving contemporaneously with the Grey Gneiss, could be explained by either a shallow- or deep-level control on the intensive parameters, which in turn affected the fractionation assemblage. However, on closer examination of the amphibolite suite, it appears such iron-enrichment is not comparable with examples such as those listed above, and requires further explanation.

Figure 4.9. SiO<sub>2</sub> versus FeO<sup>t</sup>/MgO for selected continental arc and continental rift data (grey circles) compared with the Sauda Grey Gneiss (black diamonds) and amphibolite (white circles) suites. Data from the Georoc database (http://georoc.mpch-mainz.gwdg.de)

Figure 4.9 shows data from the Grey Gneiss and amphibolite suites compared to published data from a variety of continental arc and continental rift settings. Such extreme iron enrichment in basaltic lithologies is rare to non-existent in arc settings, but is more common in continental rift settings, particularly in the Columbia River Flood Basalts (CFB). Such iron-rich mafic rocks are commonly referred to as ferrobasalts, notable examples include oceanic islands (Galapagos, Baitis & Lindstrom 1980; Thingmuli, Carmichael 1964), continental rifts (Snake River Plain, Leeman et al. 1976), layered intrusions (Skaergaard; Wager 1960) and residual magmas associated with

anorthosite massifs (Laramie Anorthosite Complex; Scoates et al. 1996). These examples exhibit lithologies with similar iron contents to that recorded in the amphibolites suite (Figure 4.10a).

Extreme iron enrichment can be achieved by differentiation of parent magmas involving no Fe-Ti crystallization but dominant plagioclase crystallisation in the early stages of differentiation, such that iron is enriched, and silica is not enriched and possibly even depleted. This differentiation has been reproduced experimentally at low pressure to explain the origin of oceanic tholeiites and the Skaergaard trend (e.g. Spulber & Rutherford 1983; Toplis & Carrol 1985; Snyder et al. 1993; Thy et al. 2006), but does not explain formation in settings with thick continental crust such as the Snake River Plain. Recent studies however have focused on this latter setting; experiments with low water contents at a variety of pressures have been conducted to try and reproduce the compositions seen in the Snake River Plain and in other iron-enriched magma series (Villiger et al. 2004; Nekvasil et al. 2001; 2004; Whitaker et al. 2007; 2008). The results from Whitaker et al. (2007) are displayed in figure 4.10b; the experiments were conducted on an olivine tholeiite with reducing conditions ( $\Delta$ FMQ ~ -2), low water activity (0.05 wt% H<sub>2</sub>O), and pressures from 0 to 9.3 Kbar. At all pressures, magma differentiation involved significant iron enrichment and a lack of silica enrichment. Also shown on figure 4.10b are experimental data from Sisson et al. (2005), which are similar to the original calc-alkaline experiments of Sisson & Grove (1993); iron enrichment during magma differentiation varies according to a change in oxygen fugacity, but silica is highly enriched leading to calc-alkaline differentiation trends. In summary, experimental data show that water content has a critical control on fractionating assemblage, and thus, whether tholeiitic or calcalkaline trends are followed. The amphibolite suite must have formed in conditions with very low water activity similar to that advocated for continental rift ferrobasalts, and the Grey Gneiss suite likely formed in hydrous conditions similar to those recorded in modern arcs.

The threshold water content at which iron-enriched tholeiitic trends will form instead of more typical silica-enriched calc-alkaline trends, is not well constrained, but is inferred to be between 0.5 and 0.8 wt% H<sub>2</sub>O at 9.3 Kbar using continental rift starting materials (Nekvasil et al. 2001). The scarcity of iron-enriched magma series occurring in volcanic arcs suggests that the crust in this setting typically has a higher water content than this threshold. Where iron-enriched compositions are more common, e.g. oceanic islands and continental rifts, there is typically a plume-related source advocated for formation of the magma series; this mantle source is inferred to be drier and more reducing than in arc settings (e.g. Christiansen & McCurry 2009), and in some examples, such as the Etendeka-Parana flood basalts province, the iron-enrichment may even be enhanced by further processes such as iron-rich streaks in the mantle plume (Gibson et al. 2000; Ewart et al. 2004).

Figure 4.10. A) SiO2 versus Fe\* (Frost et al. 2001) for the Sauda Grey Gneiss and amphibolite suites compared with data from Thingmuli (Iceland; Carmichael 1964), the Craters of the Moon suite in the Snake River Plain (Stout et al. 1994; Hooper 2000; McCurry et al. 2008; Putirka et al. 2009), the Sherman Batholith (Proterozoic tholeiitic A-type pluton in Wyoming; Frost et al. 1999), and the Sybille intrusion (residual tholeiitic rocks associated with the Proterozoic Laramie Anorthosite Complex, Mitchell et al. 1996; Scoates et al. 1996).

B) The Sauda Grey Gneiss and amphibolite suite compared with experimental data using anhydrous olivine tholeiite (Whitaker et al. 2007), hydrous medium-K high-Al basalt (Sisson et al. 2005) and hydrous peridotite (Gaetani & Grove 1998). Grey lines show the approximate differentiation trends for experimental data; black dotted line shows the evolution of the amphibolite suite.

The contemporaneous formation of continental rift-like tholeiitic (ferroan) amphibolites (at least on this coarse Precambrian timescale), with the subduction-related calc-alkaline (magnesian) Grey Gneiss suite, is rather anomalous within the global rock record. As stated previously, the

compositional difference between the two suites is likely related to changes during magma differentiation, changes in source conditions, or changes in the source material. The previous sections have discussed changes in sources conditions that form tholeiitic versus calc-alkaline magma series. To further assess whether different sources were involved, the trace element content of the two suites can be examined; this is shown in figure 4.11 using primitive mantle normalized plots and trace element ratio binary plots. The amphibolites feature similar LILE and HFSE enrichment to the Grey Gneiss suite, similar LILE/HFSE ratios, and a similar to slightly lessnegative Nb anomaly. In the Th/Yb versus Ta/Yb and the Nb/Y versus Zr/Y plots, the amphibolites overlap the Grey Gneiss, and exhibit similar degrees of subduction-zone related enrichment. The data indicate a similar subduction-zone related source for the amphibolites as for the Grey Gneiss; if the source for the amphibolites was related to a mantle plume or asthenospheric mantle, then the data should fall within the tramlines on the Ta/Yb versus Th/Yb and Zr/Y versus Nb/Y diagrams, and should lack a Nb anomaly.

On the basis of comparison with experimental data and geochemical data, the petrogenesis of the amphibolites suite is inferred to have involved a source similar to that of the Grey Gneiss, but with crystallisation under different intensive parameters, namely very low water content (<0.5% H<sub>2</sub>O) and reducing conditions ( $\Delta FMQ \sim -1$  to -2). How such conditions prevailed in an arc setting remains speculative, and due to the lack of other comparable suites in the rock record, may be a rare sequence of events. One similar example but with less extreme end-member compositions, may provide a more recent analogue however for the setting of this Telemarkian magmatism. Shuto et al. (2006) describe a model for the petrogeneses of magmatic suites that developed during the opening of the Japan sea; in their model, the early stages of the Japan sea opening (Early Miocene) involved asthenospheric mantle upwelling with partial melting of the overlying lithosphere and continental rifting; partial melting of the lower crust forming continental-rift silicic magmas. This process of continental rift magmatism is similar to that advocated for the Rjukan rift in central Telemarkia (Menuge & Brewer 1996; Sigmond et al. 1997; Slagstad et al. 2009), in which partial melting of crust formed the Rjukan rhyolites at ~1500 Ma (Dahlgren et al. 1990). The geochemistry of basaltic magmatism that occurred in the Rjukan Rift (Vemork formation) is shown in figure 4.11 for comparison; compared to the Grey Gneiss and amphibolites, the Vemork basalts are much less LILE-enriched, lack a Nb anomaly, and fall within the tramlines in the Zr/Y versus Nb/Y plot, therefore they are compatible with an origin in the asthenospheric mantle.

The opening of the Rjukan rift in the Telemark Sector (and the related asthenospheric mantle upwelling), occurred contemporaneously with the amphibolite and Grey Gneiss magmatic suites in the neighbouring Suldal Sector. A tectonic model for the evolution of these magmatic suites is shown in figure 4.11. It is inferred that extension of the overriding plate (Telemarkia) that was

likely related to slab-rollback, caused localized extension of the crust forming the Rjukan rift (Slagstad et al. 2009). Extension of the lithosphere allowed uprise of asthenospheric mantle, this uprising mantle produced the Rjukan rhyolites via crustal anatexis, and later produced basaltic magmatism after further crustal extension. At the same time, dehydration melting in the mantle wedge above the subducting slab was producing typical arc magmatism (Sauda Grey Gneiss). At certain points in time, dry and reducing conditions existed in the zone of melt generation, such that the tholeiitic amphibolite suite was produced. Differentiation of the tholeiitic magma series may have been aided by crustal extension, allowing rapid magma uprise without crustal contamination (e.g. Hora et al. 2009). The prevalence of reducing and dry conditions may have been aided by the uprise of asthenospheric mantle; this mantle uprise is interpreted to be a source of heat but not a source of material for the generation of the amphibolites.

As stated above, the existence of dry and reducing conditions in a supra-subduction setting is rare. Known water contents of arc magmas are up to 6 wt% (Sisson & Layne 1993). The average oxygen fugacity of arc magmas is estimated to be  $\Delta$ FMQ -1 to +2 whereas the upper mantle has a range from  $\Delta$ FMQ -4 to +2, and the lower mantle is much more reducing at  $\Delta$ FMQ <-5 (Carmichael & Ghiorso 1990; Parkinson & Arculus 1999; McCammon 2005; Rowe et al. 2009). The oxygen fugacity of lower arc crust has been estimated for the Talkeetna arc to be  $\Delta FMQ + 1 \pm 1$  (Behn & Kelemen 2006). The increased oxygen fugacity in arc magmas relative to the mantle has been attributed to the addition of volatiles derived from dehydration of the subducting slab; in a study of volcanic arc magmas from the Cascades arc, oxygen fugacity was correlated with fluid-mobile trace element and LREE contents (Rowe et al. 2009). In the Taupo volcanic zone of New Zealand, oxygen fucacity is correlated with slab-derived fluids such as Ba and Cl (Deering et al. 2010). In the latter study a temporal change is observed from wet-oxidising magmas to dry-reducing magmas, and is thus related to a decrease in the flux of subduction-related volatiles. Average oxygen fugacity in the Taupo magmas ranges from  $\Delta FMQ + 0.5$  to +1.5, and the change occurs over ~100,000 years. A temporal change like this may have existed in the Suldal arc, but would be difficult to distinguish on a Precambrian timescale. The range in oxygen fugacity in this example is much less extreme than that required to produce the variation between the iron-enriched tholeiitic amphibolite suite and the calc-alkaline Grey Gneiss suite.

The cause of dry and reducing conditions during early differentiation of the amphibolite suite remains speculative, since its geochemistry is indicative of subduction-zone enrichment in

Comparison between basaltic compositions

Figure 4.11. Schematic model for the tectonic setting of ~1500 Ma magmatism in Telemarkia. The magnesian Sauda Grey Gneiss suite is formed by melting in the mantle wedge with a subduction-zone fluid and sediment flux typical of continental arcs; the ferroan amphibolite suite had a similar parent magma but formed in anhydrous and reducing conditions. The magnesian rhyolites (Tuddall Fm) of the Rjukan Rift in the Telemark Sector formed by crustal anatexis fluxed by asthenospheric mantle, and the basalts (Vemork Fm) formed after underplating by asthenospheric mantle. Plots of mafic end-members of the three suites are shown to compare geochemistry; the Grey Gneiss and amphibolite suites have similar signatures (subduction-related), and the Vemork Fm has a significantly diferent signature (asthenospheric mantle input). Subduction zone model modified from Shuto et al. (2006); FeOt/FeOt+MgO versus SiO2 after Frost et al. (2001); Th/Yb versus Ta/Yb after Pearce (1982); Nb/Y versus Zr/Y after Fitton et al. (1997).

fluids/volatiles. A possible explanation is that at certain points in time during the evolution of the Suldal Arc, basaltic parent magmas forming in a hot deep crustal zone were dehydrated; this

occurred through a decrease in subduction-zone fluid flux, and to successive melt production and heating from magmatic underplating; this would have left the magma dehydrated but not refractory (Landenberger & Collins 1996), and would also have a higher solidus than normal hydrous arc magma. The extra heat required for melting of dehydrated mafic crust was likely provided by asthenospheric mantle upwelling; also, an extensional setting meant that melts could intrude along weaknesses into the upper crust, and thus avoid assimilation of surrounding wet and oxidizing crust.

### 4.5 Discussion

#### 4.5.1 Origin of A-type granites.

If the tholeiitic (ferroan) amphibolites differentiated into granitic compositions, then based on their geochemistry these would fall into the category of A-type granites (low CaO, high Fe/Mg and Ga/Al, and enriched incompatible elements); they would thus provide a genetic link between tholeiitic mafic magmas and A-type felsic magmas. The amphibolite suite has differentiated into granodioritic compositions that are coarse-grained porphryritic amphibolites bodies. At high silica contents calc-alkaline (magnesian) trends converge with ferroan trends, hindering the distinction between different granite suites (Frost et al. 2001). On the Fe\* versus SiO<sub>2</sub> plot (Figure 4.2) a couple of the granitoids fall on the ferroan trend; these coarse-grained porphyritic granitoids are similar to other granites in the region, including those that are Sveconorwegian in age. Thus, it cannot be determined without further dating, whether the amphibolite suite has fully differentiated into A-type granites, or whether such lithologies in the region are only related to Sveconorwegian magmatism.

The connection between tholeiitic (i.e. ferroan and anhydrous source) magmas, and A-type granites, is known as the tholeiite connection (Frost & Frost 1997). This model is postulated for the petrogenesis of Proterozoic Rapakivi-type granites (e.g. Sherman Batholith, US), and involves the intrusion of tholeiitic basalts into the lower crust, remelting of these basalts, and the intrusion of subsequent melts into the middle crust to form A-type plutons. This is a similar mechanism to that proposed for the amphibolite suite, except that in the Frost & Frost (1997) model, an asthenospheric source is required for the initial intrusion of tholeiitic basic magmas into the base of the crust. In the model proposed here an asthenospheric mantle is required for heating but not for the source; the tholeiitic source is derived from dehydrating of normal depleted mantle arc magmas.

A-type granites are commonly associated with extensional and 'anorogenic' settings (Windley 1993; Bonin 2007). This study has indicated the formation of A-type magmas in an arc setting; this has previously been recorded in Proterozoic arc settings (e.g. Slagstad et al. 2004; Zhao et al. 2008). In the Mesoproterozoic Muskoka domain in the Grenville province, Slagstad et al. (2004) suggest intra-arc extension has allowed the sourcing of asthenospheric mantle for formation of tholeiitic

parent magmas. In a Neoproterozoic arc on the edge of the Yangtze block, Zhao et al. (2008) suggest A-type plutons have formed by remelting of TTG-type crust that has been dried out (i.e. charnockitisation), by sustained heating from a magmatic underplate. The model proposed here includes elements of both of these examples, i.e. intra-arc extension, dehydration of mafic crust induced by magmatic underplating, and asthenospheric mantle upwelling to provide further heat for melting of the dehydrated crust.

## 4.6 Conclusions

The major, trace and REE trends within the Sauda Grey Gneiss suite suggest that it formed by multiple stages of fractionation at different levels in the crust, in a deep hot crustal zone setting (Annen et al. 2006). The fact that both ferroan (amphibolites) and magnesian (Grey Gneiss) trends are recorded in upper crustal intrusive rocks, suggests that melts were able to fractionate in relatively closed-systems. However, in this hot crustal environment, it is likely that some magma batches underwent mixing; the magma mingling seen in the field is evidence of mafic magmas intruding more felsic magma bodies. Partial melting of crystallised magma bodies by the heat of later intrusions may occur in this environment. The production of evolved rocks via fractional crystallisation requires large volumes of residual cumulate rocks to be produced. These may be present in the lower crust, but also may have been returned to the mantle (Kay & Kay 1985; Arndt & Goldstein 1989).

The geochemistry of the magma suites suggests formation in a volcanic arc setting. The degree of LREE enrichment is significantly greater than that observed in oceanic island arcs (e.g. Talkeetna, Clift et al. 2005; Greene et al. 2006), and complete differentiation from mafic to felsic compositions requires a greater differentiation column than typical oceanic island arcs. Thus, the Suldal arc probably developed on thickened crust, such as in a mature island arc or continental arc. However, the geochemistry of the arc rocks is compatible with fractional crystallisation of mantle-derived basalt in relatively closed-systems, without obvious assimilation of previously formed crust. Although the data cannot exclude the existence of pre-existing crust, they do not require it. Bimodal continental rift magmatism in the adjacent Telemark Sector, occurring contemporaneously with arc magmatism in the Suldal Sector, suggests that the crust was undergoing extension during the ~1.5 Ga period. Thus, a thin ensiliac crust is interpreted to be the most likely candidate for the substrate of the Suldal Arc. Arcs developed on ensiliac crust can occur outboard of continental shields as continental ribbons, or on attenuated parts of continental crust; both of these features are typical of retreating accretionary orogens (Cawood et al. 2009).

Highly iron-enriched tholeiitic magma series were able to differentiate during the evolution of the Suldal arc. Such compositions are rare in the rock record, and in continental settings are typically

related to anorogenic plume-related magmatism. The formation of such compositions is postulated to be a function of very dry and reducing conditions existing during magma differentiation; the cause of such conditions in a supra-subduction setting is anomalous, but linked to dehydration and subsequent melting, both possibly as a consequence of asthenospheric mantle upwelling that produced coeval continental rift magmatism in the adjacent Telemark Sector.

Table 4.1. Results of Rayleigh fractional crystallisation modelling of REE contents in the Sauda Grey Gneiss. Each successive melt is modelled at 20% fractional crystallisation. Partition coefficients from Arth (1976), Fujimaki et al. (1984), Dostal et al. (1983), Shock (1979), Gill (1981) and Philpotts & Schnetzler (1970).

## Continental recycling in arc magmas: Hf-O isotope constraints on Telemarkian (1.52-1.48 Ga) magmatism

Aim - In this chapter, zircon Hf and O isotope data from various arc-type lithologies from the Suldal Sector are presented. The data are used to constrain the possible crustal and mantle components that have contributed to  $\sim$ 1.5 Ga arc magmatism in Telemarkia, and deduce the amount of continental growth that has occurred during this magmatic episode.

## 5.1 Introduction

Recent advances in the in-situ measurement of isotopes in the accessory mineral zircon have lead to its common use as a tool for refining the petrogenesis of igneous rocks (e.g. Hawkesworth & Kemp 2006). The ability to measure both hafnium and oxygen isotopes on zircon grains that have also been dated by U-Pb, allows for the discrimination of multiple magmatic sources that typically cannot be constrained using whole-rock methods. For example, U-Pb zircon ages can point to older crustal contaminants that have added inherited zircons to a magma, Hf isotopes can be used to determine the crustal residence age of the magma that a zircon crystallised in, and oxygen isotopes can be used to constrain where older components were recycled into the magma (in the mantle or in the crust).

The recycling of pre-existing continental crust, including sedimentary material, to arc magmas has long been recognized (e.g. Armstrong 1971; Hildreth & Moorbath 1988; Plank & Langmuir 1993). Numerous studies have sought to constrain whether continental crust has been recycled into the arc magmas in the mantle, via subduction of sediments, or in the crust, via contamination and assimilation (e.g. Hawkesworth et al. 1979; Thirlwall & Graham 1984; Gasparon et al. 1994). Both of these processes likely occur together in the same subduction zone; however it is useful to discriminate between them to determine the volume and rate that previously formed continental crust is being recycled. The end-member processes are termed mantle recycling and intracrustal recycling; the latter can be broken down into infracrustal recycling, whereby previously formed igneous crust (such as ancient underplated material) is recycled into the magma. Studies aiming at differentiating these processes have commonly combined radiogenic isotopes (e.g. Sr, Nd, Hf) with a stable isotope (O) (e.g. James 1981; Davidson 1985).

Determining the mantle versus crustal input to different granitoid types in different geodynamic settings has long been a focus of petrogenetic studies. The geochemical classification of granitoid suites is commonly used to infer tectonic settings and/or mantle versus crustal sources. For example, with the alphabet classification scheme (Chappell & White 1974), I-type granites typically

have an inferred igneous and/or mantle source and occur in arc settings, S-type granites have inferred sedimentary sources and occur in collisional settings, and A-types have inferred mantle or mixed sources and occur in anorogenic sources (see reviews by Barbarin 1999; Frost et al. 2001). However, recent studies combining zircon U-Pb, Hf and O, have demonstrated that both sedimentary and mantle material have been involved in the petrogenesis of all of these granite types in a variety of settings (e.g. I-type, Kemp et al. 2007; S-type, Appleby et al. 2009; A-type granites, Be'eri-Shlevin et al. 2009). Thus, granitoids with a variety of geochemical signatures and in a variety of tectonic settings may involve both recycling of previously formed continental crust and formation of new crust by juvenile mantle input.

The crystalline basement in SW Fennoscandia comprises various Palaeo- to Mesoproterozoic terranes that comprise deformed plutonic and volcanic arc-like lithologies, and have been reworked during the Sveconorwegian (Grenvillian) and Caledonian orogenies (e.g. Gaál & Gorbatschev, 1987; Bingen et al. 2008a). The evolution of the ~1.7 to 1.5 Ga crust can be described by two endmember models: 1) where Palaeoproterozoic crust underlies the entire region and has been recycled during younger magmatic episodes (Andersen et al. 2002b, 2004a, 2009b), or 2) where the various terranes represent accreted juvenile arcs with limited contribution from older material (Brewer et al. 1998; Åhäll & Connelly 2008). Various isotope data point to a contribution from Palaeoproterozoic crust to Gothian (~1.7-1.55 Ga) and younger magmatism (1.2-0.93 Ga; Andersen 1997, 2001, 2002b, 2004a, 2007b, 2009b; Andersen & Griffin 2004), but the lack of isotope data from ~1.5 Ga Telemarkian crust hinders the testing of the above models; to resolve this, this study presents U-Pb, Hf and O data from Telemarkian (~1.5 Ga) magmatic rocks in the Suldal Sector, which are used to constrain if and what older crust has been recycled during their petrogenesis.

## 5.2 Geological Setting

The Fennoscandian Shield comprises an Archaean core in the northwest; surrounding this are younger arcs and microcontinents that amalgamated during the Svecofennian orogeny at ~ 2.1-1.9 Ga (Korja et al. 2006; Lahtinen et al. 2009). At ~1.85 Ga a subduction zone initiated on the southwest margin (present-day position) of the continent, producing the Transcandinavian Igneous Belt (TIB; see Högdahl et al. 2004). The terranes to the southwest of the TIB that comprise the Southwest Scandinavian Domain (SSD), can be interpreted as forming in continental and island arcs along a long-lived subduction margin that progressively moved away from the Fennoscandian continent (Åhäll & Connelly 2008), in a retreating accretionary orogen (Cawood et al. 2009).

The SSD comprises terranes (senso lato) aged  $\sim$ 1.69 to 1.48 Ga that progressively young to the west. The youngest of these, Telemarkia, makes up the crust west of the Oslo Rift (Bingen et al. 2005b). The oldest identified igneous unit within Telemarkia is the 1.55 Ga Åsen metatonalite

(Pedersen et al. 2009); this is the only unit older than 1.52 Ga, and its origin remains uncertain. The main continental growth episode of the Telemarkia terrane is defined as 1.52-1.48 Ga (Bingen et al. 2005b; 2008a), and is known from dating plutonic and volcanic orthogneisses from across the region. Other major tectonostratigraphic units within Telemarkia include the ~1.5 Ga Vestfjorddalen supergroup which has been related to continental extension behind a subduction margin (Slagstad et al. 2009), supracrustal sequences dated at 1260-1220 and 1170–1140 Ma that are also related to extensional settings behind a subduction margin (Bingen et al. 2002; Brewer et al. 2004), and early- to late-Sveconorwegian intrusions dated between 1.05 and 0.93 Ga (Andersen et al. 2002a, 2007a; Bingen & van Breemen 1998; Schärer et al. 1996). Various sedimentary units within Telemarkia that were deposited between ~1.6 and 1.1 Ga, comprise Palaeoproterozoic and late Archaean detrital zircons (Åhäll et al. 1998; de Haas et al. 1999; Bingen et al. 2001b, 2003); this suggests that during the Mesoproterozoic the terrane was located near to an older continent.

Figure 5.1. A) Lithotectonic domains of SW Fennoscandia. Ha = Hardangervidda Sector, Su = Suldal Sector, RVA = Rogaland Vest-Agder Sector, Tele = Telemark Sector, K = Kongsberg terrane, MZ = Mylonite Zone, MUSZ = Mandal-Ustaoset Shear Zone. B) Geological sketchmap showing the sample localities from the Suldal Sector along with U-Pb ages and average Hf and O isotope values. (Modified from Bingen et al. 2005b).

The samples in this study are taken from the Suldal Sector in and around the Sauda and Suldal communes (Figure 5.1), except for one sample from further south in the Rogaland Vest-Agder Sector. The basement in these areas comprises variably fine to coarse-grained lithologies metamorphosed in amphibolite-facies, and that are interpreted to represent different exposures through an arc complex (Chapter 2). The geochemistry of these lithologies is compatible with formation in an arc setting via fractional crystallisation of mantle-derived mafic melts (Chapter 4). Brief sample descriptions are given in Table 5.1; further details of samples collected within this study (SAX-XX sample number), are provided in Chapter 3. Separated zircons have a range of morphologies, but are generally prismatic, oscillatory-zone and elongate, as is typical of igneous zircons (Figure 5.2). The more mafic lithologies (SA7-86 and ROG525) exhibit larger zircons which were fragmented during separation, and feature less distinct oscillatory-zoning or are sector zoned. Distinctive core and rim/overgrowth relationships are lacking in all samples; discontinuities in zoning do exist in some grains, but the style of zoning across these is similar, suggesting an origin related to replenishment of magma during crystallisation, as opposed to overgrowth on inherited zircons. U-Pb ages where obtained from multiple growth zones are similar in age also (see Chapter 3; Slagstad & Marker 2009, unpublished data).

## 5.3 Analytical Methods

#### 5.3.1 Zircon U-Pb isotopes

Zircons were analysed either by LA-ICP-MS at the NERC Isotope Geosciences Laboratory, UK, (data presented in chapter 3), or by ion microprobe at the NORDSIM facility, Sweden (unpublished data; Slagstad & Marker 2009). <sup>207</sup>Pb/<sup>206</sup>Pb ages are given in Table 10.18.

#### 5.3.2 Zircon Hf isotopes

Lu-Hf isotope analyses were determined at the NERC Isotope Geosciences Laboratory, UK, using a Nu-Plasma HR MC-ICP-MS coupled to a 193 nm solid state (UP193SS, New Wave Research) laser ablation system. Helium gas was added to the laser ablation cell, and argon gas was added after ablation via a NU-Plasma DSN-100 desolvating nebuliser, whilst aspirating a 2% HNO<sub>3</sub> +0.1 molar Hf acid solution to help maintain constant plasma conditions.

The analyses were performed on zircons mounted in epoxy blocks; all mounts were cleaned with weak acid before Hf analysis, and mounts that had been used for SIMS analyses had their gold coating removed prior to cleaning. Analyses were carried out on top of the ion-microprobe or laser-ablation pit when possible, so that Hf analysis could be paired with the dated portion of the zircon.

The isotopes <sup>173</sup>Yb, <sup>174</sup>(Yb, Hf), <sup>175</sup>Lu, <sup>176</sup>(Yb, Lu, Hf), <sup>177</sup>Hf, <sup>178</sup>Hf, and <sup>179</sup>Hf were measured on Faraday cups in a static sequence. The isobaric interference of <sup>176</sup>Yb was corrected using the method of Nowell & Parrish (2001); JMC475 Hf standard solutions were measured prior to each analytical session which were variably doped with Yb (0 to 40ppb), the true value of <sup>176</sup>Yb/<sup>173</sup>Yb is then calculated using a regression. This true <sup>176</sup>Yb/<sup>173</sup>Yb value is used to subtract <sup>176</sup>Yb from the 176 peak. The interference of <sup>176</sup>Lu on <sup>176</sup>Hf was corrected by measuring the interference-free <sup>175</sup>Lu isotope and using a value of 0.02653. Corrections were applied during each analysis after an inverse mass bias correction using the measured <sup>179</sup>Hf/<sup>177</sup>Hf ratio, this allows for absolute differences between the Hf and Yb mass bias. The <sup>178</sup>Hf/<sup>177</sup>Hf stable isotope ratio is used to monitor data quality.

A spot diameter of 50  $\mu$ m, 10 Hz repetition rate and ablation time of 60 seconds were used, resulting in total Hf signals of 5 to 9V. All data were normalised to the <sup>176</sup>Hf/<sup>177</sup>Hf of the JMC475 reference solution assuming a value of 0.282160. The <sup>176</sup>Lu/<sup>177</sup>Hf ratio was normalised to the reference material using values of 0.000311 for 91500 and 0.000042 for Mud Tank (Woodhead & Hergt 2005). Data were reduced off-line using time-resolved analyses; this allows for the selection of stable portions of analyses and the identification of ablation through different growth zones or into the epoxy mount. All uncertainty components, including those for age and normalisation, were factored into the final uncertainty quoted. Analytical uncertainties for unknowns were propagated by quadratic addition to include the standard error of the mean of the analysis and the

reproducibility of the primary ablation reference material. The reproducibility of the standards was better than 1 epsilon unit; the final analytical uncertainty of the unknowns is typically between 1 and 2 epsilon units.

Figure 5.3. Reproducability of the <sup>176</sup>Hf/<sup>177</sup>Hf ratio in secondary standards across all of the analytical sessions. Recommended values from Jackson et al. (2004), Woodhead & Hergt (2005) and Sláma et al. (2008).

Hf analyses were conducted on concordant (>95 % concordance) grains where possible; less than 10% of the data are obtained on discordant grains. The  ${}^{176}\text{Hf}/{}^{177}\text{Hf}_{initial}$  value measured on discordant grains is within error of the average  ${}^{176}\text{Hf}/{}^{177}\text{Hf}_{initial}$  of the sample, indicating that any disturbance of the Lu-Hf system during events that have caused lead-loss is neglible, and thus that the spread in  ${}^{176}\text{Hf}/{}^{177}\text{Hf}_{initial}$  within each sample does not represent metamorphic disturbance.

During analytical sessions in 2009, the measured  ${}^{178}$ Hf/ ${}^{177}$ Hf ratio was sometimes below the recommended value (1.4723; Patchett & Tatsumoto 1981). In some samples  ${}^{176}$ Hf/ ${}^{177}$ Hf<sub>initial</sub> correlates with  ${}^{178}$ Hf/ ${}^{177}$ Hf, whereas in other samples  ${}^{176}$ Hf/ ${}^{177}$ Hf<sub>initial</sub> seems unaffected (Table 10.18). The analyses where the  ${}^{178}$ Hf/ ${}^{177}$ Hf ratio is significantly low have  ${}^{176}$ Hf/ ${}^{177}$ Hf<sub>initial</sub> values that are within analytical uncertainty (2 $\sigma$ ) of the sample mean; thus these data have not been rejected, but it is worth noting that the total range in  $\epsilon$ Hf for some samples maybe over estimated due to this analytical error.

Epsilon Hf values were calculated using the decay constant  $\lambda$ (<sup>176</sup>Lu)=1.867\*10<sup>-11</sup> (Söderlund et al. 2004), CHUR parameters of Bouvier et al. (2008), and the depleted mantle model (DM) of Griffin

et al. (2000); the depleted mantle model of Pietranik et al. (2009) is also shown in figure 5.7 for comparison. Model ages are calculated using  $^{207}$ Pb/ $^{206}$ Pb ages with  $^{176}$ Hf/ $^{177}$ Hf<sub>initial</sub> and  $^{176}$ Lu/ $^{177}$ Hf ratios. The Lu/Hf ratio in a zircon is typically much lower than that of the magma that the zircon crystallised in, therefore, single-stage model ages calculated using the Lu/Hf of the zircon (T<sub>DMZ</sub>) will be erroneously low. An alternative method is to calculate a two-stage model age using the Lu/Hf ratio of the whole-rock from which the zircon was extracted, as this provides a best estimate for the Lu/Hf of the magma. Whole-rock measurements were not made during this study, thus, known average Lu/Hf ratios of crustal reservoirs can be used instead. Commonly used ratios include 0.022 for mafic crust (Vervoort & Patchett 1996), 0.093 for felsic crust (Amelin et al. 1999), and 0.015 for average continental crust (Griffin et al. 2000). In this study, two-stage model ages are presented using a Lu/Hf of 0.015 (T<sub>DMC</sub>).

#### 5.3.3 Zircon oxygen isotopes

Oxygen isotope data were obtained at the University of Edinburgh, UK, using a Cameca ims-1270 ion microprobe following methods outlined in Appleby et al. (2009) and Kemp et al. (2007). Analysed zircons were mounted in epoxy blocks, cleaned in weak acid and gold-coated. The analyses were conducted after U-Pb and Hf analyses, so the mounts were lightly polished using diamond paste to remove any significant topography caused by previous ablation.

A 6nA primary <sup>133</sup>Cs<sup>+</sup> ion beam with a diameter of ~20  $\mu$ m was used, with the charge being neutralised using a normal-incidence electron flood gun. Secondary ions were extracted at 10kV. <sup>18</sup>O<sup>-</sup> and <sup>16</sup>O<sup>-</sup> ions were measured simultaneously on dual Faraday cups. Each analysis involved presputtering for 50 seconds, followed by data collection in 10 cycles, with 4 seconds of acquisition per cycle. The secondary yield of <sup>18</sup>O was typically between 5\*10<sup>6</sup> and 8\*10<sup>6</sup> counts per second.

Figure 5.4. Reproducability of  $\delta^{18}$ O in the 91500 primary standard across the analytical session. Recommended value from Valley (2003).

To correct for instrumental mass bias and instrumental drift all data were normalised to 91500 ( $\delta^{18}$ O = 10.07 ± 0.03‰; Valley 2003). This standard zircon was analysed in blocks of 5 to 10 after every 10 to 20 analyses of unknowns. The beginning of each analytical session involved measurement of 40-60 analyses of a combination of 91500 and in-house standards (KIM/Temora). The unknown analyses were normalised to the daily average <sup>18</sup>O/<sup>16</sup>O value obtained for 91500, or if instrumental drift was recognised, the data were normalised to the linearly interpolated <sup>18</sup>O/<sup>16</sup>O value derived from analyses of the bracketing 91500 standard. The external precision based on analysis of the standard was 0.69‰ (2 $\sigma$ ) across the whole analytical session (Figure 5.4). This value is used as the final uncertainty on the unknowns as it gives the most conservative estimate of the uncertainty.

## 5.4 Results

#### 5.4.1 Zircon Hf isotopes

The results of the Hf analyses are plotted in Figure 5.5. Each sample has a mean value falling between CHUR and depleted mantle (DM); the total  $\epsilon$ Hf range across the samples is from ~-1 to +10. The range in  $\epsilon$ Hf for each sample varies from ~1.5 to 6 epsilon units (MSWD 0.4 to 5); for some of the samples this range is within analytical uncertainty (MM36631, MM36676, SA3-60, SA7-91; MSWD 0.4 to 1.4). None of the samples have outliers which are not within error ( $2\sigma$ ) of other analyses within the sample population. 20 of the analyses lack U-Pb data from the analysed zircon; however, the U-Pb data from these samples suggests the zircons represent single igneous populations (Chapter 3), and therefore the intrusion age provides a robust estimate for the age of crystallisation of the zircons. The lack of anomalously low  ${}^{176}$ Hf/ ${}^{177}$ Hf<sub>initial</sub> values in any of the samples, suggests that none of the analysis were conducted on grains inherited from much older crust (>300 Myrs).

Multiple Hf analyses from the same zircon grain are within analytical uncertainty of each other (see Figure 5.2 & Table 10.18); the maximum variation between multiple analyses that are aimed at the same portion of zircon is 2.03 epsilon units with an average variation of only 0.76 epsilon units (n=11), the maximum variation between analyses on different parts of the same zircon grain is 1.89 epsilon units with a average of 0.96 epsilon units (n=8). Thus, in this dataset there is no evidence for variation between outer and inner zircon zones, suggesting little evolving heterogeneity in the magmas, in contrast to selected previous studies (Kemp et al. 2007; Appleby et al. 2008; Be'eri Shlevin et al. 2009).

The data exhibit a subtle temporal correlation, with  $\epsilon$ Hf decreasing with decreasing intrusion age (Figure 5.5). The data do not exhibit a clear correlation between  $\epsilon$ Hf and SiO<sub>2</sub>, the latter being used to represent the degree of magma differentiation. The two most mafic samples (ROG525 and SA7-86) have mean  $\epsilon$ Hf values of ~+6 and ~+5.5 respectively, which are similar to the mean values of the most differentiated samples (SA7-91, SA3-60). The most enriched (lowest  $\epsilon$ Hf) samples are Ro-

102B (migmatitic grey gneiss), SA3-04 (porphyritic granodiorite), and MM2235 and MM2241 (dacitic quartz-feldspar gneisses).

Two-stage model ages using a Lu/Hf of 0.015 ( $T_{DMC}$ ) for the samples range from 1530 to 2173 Ma, with the average of each sample ranging from 1611 to 2016 Ma. The model ages are ~100 to 500 million years older than the intrusion ages.

Figure 5.5. Results of in-situ Hf analyses. (A)  $\epsilon$ Hf<sub>(initial)</sub> plotted against arbitary units, for each sample the weighted mean and 2s.e. are shown as a black solid line and block dotted lines respectively. (B)  $\epsilon$ Hf<sub>(initial)</sub> versus the intrusion age of the sample. Error bars are 2s.d. of the mean (C)  $\epsilon$ Hf<sub>(initial)</sub> versus whole-rock SiO<sub>2</sub>. Error bars are 2s.d. of the mean. DM is depleted mantle model of Griffin et al. (2000) and CHUR uses values according to Bouvier et al. (2008).

#### 5.4.2 Zircon oxygen isotopes

A subset of 8 samples were analysed for  $\delta^{18}$ O (Figure 5.6). The average  $\delta^{18}$ O of each sample varies from +5.43 ± 0.9 to +8.65 ± 1.15 ‰. Five of the samples have variation which does not exceed analytical uncertainty (ROG525, SA3-04, SA3-60, SA7-86, SA7-91; MSWD = 0.7 to 1.7), and two of the samples have variation slightly outside of the analytical uncertainty suggesting real

geological heterogeneity (MM2235, MM2241; MSWD = 2.8 & 3.3). One sample (SA7-04) exhibits a significant range in  $\delta^{18}$ O (MSWD = 22); this sample has been affected by lead-loss (see Chapter 3), has metamict and/or alteration textures visible in CL (Figure 5.2), and under normal light the zircons have an opaque milky colour. The sample was taken from near the contact with a Sveconorwegian granite which features hydrothermal mineralisation, thus, it is suggested that the variation in  $\delta^{18}$ O within this sample may represent post-crystallisation alteration.

Multiple  $\delta^{18}$ O ratios measured on the same zircon grain have variation of up to 1.01 ‰, which is slightly outside of analytical uncertainty (± 0.69 ‰), these multiple analyses were not conducted on distinguishable growth zones; such analysis of clearly different growth zones was hampered by the limited availability of material to analyse. As with the Hf analyses, the O isotopes do not exhibit a clear correlation with SiO<sub>2</sub> (Figure 5.6). The sample closest to the mantle value (5.3 ± 0.3 ‰) is a granite (SA7-91), samples with averages above the mantle value are dioritic (ROG525, SA7-86) to rhyolitic (SA3-60, MM2241), and the highest mean  $\delta^{18}$ O belongs to a dacitic gneiss (MM2235).

Figure 5.6. Results of in-situ oxygen analyses. (A)  $\delta^{18}$ O VSMOW<sub>(zircon)</sub> plotted against arbitary units; for each sample the weighted mean and 2s.e. are shown as a black line and block dotted lines respectively. (B)  $\delta^{18}$ O VSMOW<sub>(zircon)</sub> versus whole-rock SiO<sub>2</sub>. Error bars are 2s.d. of the mean. DM is depleted mantle model of Griffin et al. (2000) and CHUR values are from Bouvier et al. (2008). Symbols as in figure 5.5.

## 5.5 Discussion

Before discussing the possible mantle and crustal contributions to Telemarkian magmatism, constraints from previous studies are evaluated.

#### 5.5.1 Previous isotopic constraints

Whole-rock Sm-Nd data exist for a number of different magmatic suites within SW Fennoscandia. The Trossovdal rhyolite formation in the Sæsvatn-Valldal supracrustal belt (Suldal Sector), is postulated to have formed by crustal anatexis in a back-arc setting by mafic underplating and asthenospheric uprise (Brewer et al. 2004); whole-rock Sm-Nd analyses constrain ɛNd at 1260 Ma to be 0.6 and -3.3, equivalent to model ages of 1730 and 2000 Ma (Brewer et al. 2004). The Tuddall rhyolite formation of the Vestfjorddalen supergroup (Telemark Sector), also formed by crustal anatexis as a consequence of mafic underplating and asthenospheric uprise (Menuge & Brewer 1996); whole-rock Sm-Nd analyses give a range of model ages from 1506 to 1779 Ma. Late Gothian granitoids in the Bamble-Kongsberg and Idefjorden terranes intruding at 1522 to 1615 Ma (Hisingen Suite and Göteborg-Åmål Belt; Figure 5.7), have Nd model ages of 1570 to 1760 Ma (Andersen et al. 2002b). Late-Sveconorwegian granitoids from across SW Fennoscandia have Nd model ages in the range of 1300-1600 Ma (Andersen et al. 2001). By combining Nd with Sr and Pb isotopes, Andersen et al. (1997, 2001), have constrained the composition of a crustal component that they suggest has been involved in the source of Sveconorwegian intrusions, as well as in earlier 1.5 to 1.2 Ga magmatic suites (Andersen et al. 2002b, 2007b, 2009b; Andersen & Griffin 2004). This crustal component, termed the 'normal deep crust' (see Andersen et al. 2001), is regarded to be moderately LILE-enriched (i.e. similar to upper crust composition) and at least 1.7 Ga age.

Figure 5.7. Time (Ma) versus  $\epsilon$ Hf<sub>(initial)</sub> for zircons from SW Fennoscandia. Telemarkian data from this study; Hisingen and GAB are calc-alkaline granitoids from the Bamble, Kongsberg and Idefjorden terranes (Andersen et al. 2002b, 2004a); metagreywacke and metapelite zircons are from units deposited at ~1550 Ma in the Idefjorden terrane (Andersen et al. 2004a); TIB data are granitoids from the Transcandinavian Igneous Belt (Andersen et al. 2009a). Mantle and crustal end-members are those discussed in the text. The grey bar represent the evolution of TIB granitoids using Lu/Hf = 0.015.

In-situ Hf zircon analyses have been conducted on ~0.93-1.1 Ga Sveconorwegian intrusions from across Telemarkia, ~1.3-1.2 gneisses in the Telemark Sector, ~1.52-1.62 Ga calc-alkaline granites in the Bamble-Kongsberg and Idefjorden terranes, and ~1.85-1.66 Ga Transcandinavian Igneous Belt granitoids (Andersen et al. 2002b, 2004a, 2007b, 2009a, 2009b; Andersen & Griffin 2004;

Pedersen et al. 2009). The  $\epsilon$ Hf of the ~1.52-1.66 Ga granitoids is close to that of the depleted mantle, suggesting limited involvement of older crust (see Figure 5.7). The  $\epsilon$ Hf of <1.5 Ga magmatic rocks is compatible with mixing between depleted mantle and a source equivalent to the ~1.52-1.62 Ga granitoids. A few inherited zircons in Sveconorwegian granites, some of which are Palaeoproterozoic in age, have relatively low  $\epsilon$ Hf, and therefore cannot be produced by remelting of 1.52-1.62 Ga crust alone; these have been cited as evidence for the existence of Palaeoproterozoic crust at depth underlying southern Norway (Andersen et al. 2002b, 2009b; Andersen & Griffin 2004; Pedersen et al. 2009).

Scherstén (2002) provide the least equivocal evidence for older crust at depth, with a Re-Os age of 1887 Ma for an ultramafic lens within the Mylonite Zone that divides the Eastern Segment (comprising reworked 1.6-1.7 Ga TIB crust) from the Idefjorden terrane (1.66-1.55 Ga crust). However, this indicates that ~1.9 Ga crust may reside at depth below younger ~1.7 Ga TIB crust, but does provide evidence for older crust underlying the Telemarkia terrane.

#### 5.5.2 Zircon inheritance

The issue of inherited zircons and their origin is important, since such evidence has been used in other accretionary orogens to infer older crust existing at depth; by doing this, the interpreted amount of continental growth versus the amount of continental recycling in these accretionary orogens is dramatically decreased. Examples include the 1.7-1.8 Ga Yavapai-Mazatzal province in Laurentia (Hill & Bickford 2001), the Central Asian Orogenic Belt (Kröner et al. 2007), and the Arabian-Nubian Shield (Hargrove et al. 2006; Ali et al. 2009b). However, whether such inherited zircons can be used to infer an older deep crust is a matter of contention, for example, older zircon 'only indicates the presence of older zircons, not the presence of extensive tracts of older crust' (from a discussion in Liégeois & Stern 2010 centred on the Arabian-Nubian Shield). Liégeois & Stern (2010) suggest that because zircons are stable in the mantle, they can be introduced into juvenile magmas through a number of ways, including delamination of older crust itself. Glacial deposits have also been cited as a method of introducing older zircons onto juvenile crust (e.g. Ali et al. 2009a).

As previously stated, Sveconorwegian granitoids within Telemarkia contain some Palaeoproterozoic inherited zircons. These Sveconorwegian granitoids intrude Telemarkian basement that lack inherited zircon (see Chapter 3). Although the existence of inherited zircons has commonly been used as evidence for assimilation of older crust, the lack of inherited zircons does not indicate the non-existence of older crust.

If a magma is hot enough (typically greater than 850°C; Watson 1996), then any zircon assimilated will dissolve unless suitably large in size (>120  $\mu$ m radius); the temperature that zircon can crystallize at is dependent on the zirconium concentration of the melt (T<sub>Zr</sub>; Watson & Harrison 1983). A study by Miller et al. (2003) showed that inheritance-rich granitoids have a mean T<sub>Zr</sub> of 766°C, whereas inheritance-poor granitoids have a mean of 837°C. The T<sub>Zr</sub> of the samples in this study is variable, ranging from 712 to 859°C (Table 5.1), and spans the range of both inheritance-poor and inheritance-rich granitoids. However, Kemp et al. (2005) concluded that T<sub>Zr</sub> was unreliable at estimating the initial temperature of magma bodies, and showed that low T<sub>Zr</sub> in evolved compositions may be an underestimate, and reflect fractional crystallisation from zircon-undersaturated melts, such that the magma was initially capable of dissolving zircon, but after fractionation the residual liquids were capable of precipitating zircon.

The general lack of inheritance in the studied Telemarkian rocks can be explained by any crustal input being zircon-free (i.e. dominantly mafic), or that the melts were capable of dissolving any assimilated zircon; however, for the latter to happen in all lithologies with a range of geochemical compositions is considered unlikely. Younger Sveconorwegian intrusions feature Palaeoproterozoic inherited zircons, however, sedimentary rocks within the region have detrital zircon populations that include an abundance of Palaeoproterozoic and sometimes Archaean zircons (de Haas et al. 1999; Bingen et al. 2001b; Andersen et al. 2004b; Åhäll et al. 1998). Therefore, if Sveconorwegian granitoids assimilated such sediments prior to their crystallisation, then the need for Palaeoproterozoic igneous crust at depth is negated. In summary, the evidence from U-Pb zircon ages does not provide significant support for a Palaeoproterozoic deep crust underlying Telemarkia, unless such crust is dominantly mafic and zircon-free.

#### 5.5.3 Geochemical indicator of sources

If significant assimilation of crustal material occurs during differentiation of a magma suite, then this may impart an imprint on the magma suite's geochemistry. Detecting the input of older crust formed in an arc setting to younger arc magmas may be difficult though, especially if metamorphic recrystallisation renders mineral chemistry ineffective. If a magma assimilated, or is a partial melt of a metasedimentary rock, then it will typically be peraluminous in nature; this feature led to the discrimination of S-type granites which are highly peraluminous and have inferred supracrustal sources (Chappell & White 1974). The metaluminous to weakly peraluminous nature of the Telemarkian rocks is more typical of I-type granites, i.e. those that have igneous precursors, and suggests limited involvement of supracrustal sources. However, recent zircon isotope studies in the Lachlan orogen, have shown that supracrustal input to I-type granites can go undetected in wholerock geochemical/isotopic data (Kemp et al. 2007). The geochemistry of the studied Telemarkian rocks suggests formation by fractional crystallization of mafic parent magmas (see Chapter 4); the data do not exclude the assimilation of pre-existing crust, but do not require it.

# 5.5.4 Nature of crustal and mantle components *Zircon Hf isotopes*

The Hf model ages are 100-500 million years older than the crystallisation ages of the samples, suggesting that they did not form purely by intrusion of depleted mantle, but involved contribution from older material, or alternatively mantle that was more chondritic. Involvement of older material can occur via source contamination, whereby subducted sediments mix with depleted mantle, or by crustal contamination, whereby depleted mantle is mixed with older material during differentiation in the crust. Long-term subduction of sediments leads to enrichment of the mantle region, with a migration in composition away from pristine depleted mantle; this can lead to juvenile mantlederived magmas that have an isotope signature that has departed from the depleted mantle. Granitoids that intruded in the Gothian period (Hisingen and GAB suite; Figure 5.7), have EHf values equivalent to the depleted mantle; suggesting that during this time-period the mantle was not significantly enriched. The range of  $\varepsilon$ Hf in the Telemarkian samples is on average lower than that of the Gothian rocks (Figure 5.7), suggesting either an increase in the influence of older subducted sediment, an increase in contamination of older material in the crust, or that the crustal contaminant itself was older. The latter is not expected, since the terranes young to the west, and no older crust is exposed in the Telemarkia terrane. Mixing between depleted mantle and a component similar to Transcandinavian Igneous Belt (TIB) crust can produce the appropriate EHf values of the Telemarkian rocks (Figure 5.7).

### Zircon oxygen isotopes

The mantle is a remarkably homogeneous oxygen isotope reservoir, with igneous zircons formed in equilibrium with the mantle having an average  $\delta^{18}$ O of 5.3 ± 0.3 ‰ (Valley et al. 1998). High magmatic  $\delta^{18}$ O values (>6.5‰) are attributed to melting or assimilation of sediments, altered volcanics, or other supracrustal rocks affected by low-temperature alteration, whereas low magmatic  $\delta^{18}$ O values are attributed to incorporation of material that has undergone high temperature alteration (Valley et al. 2005). Oxygen isotopes can therefore be used to discriminate source contamination (mantle recycling) from crustal contamination (intracrustal recycling), since source contamination will lead to enriched radiogenic isotope signatures, but with oxygen isotopes retaining a mantle signature. The  $\delta^{18}O_{zircon}$  of Telemarkian rocks in this study are well above the range of mantle values (Figure 5.6), suggesting intracrustal recycling and a significant involvement of a component with high- $\delta^{18}O$ .

## Hf-O modelling

The Hf and O data form a binary array in Hf-O space (Figure 5.8), with a low- $\varepsilon$ Hf, high- $\delta^{18}$ O (crustal) end-member and a high- $\varepsilon$ Hf, low- $\delta^{18}$ O (mantle) end-member, thus input of an older crustal component can be modelled by two-component mixing, as has been achieved in previous studies combining Hf-O or Nd-O data (e.g. Peck et al. 2004; Lackey et al. 2005; Kemp et al. 2007). These

previous studies resolved AFC and bulk-mixing curves based on known crustal and mantle endmembers; in this study there is a lack of data to constrain the crustal end-member, as no older crust or metasediments are exposed within the region; however, speculative end-members can be model based on previous whole-rock studies.

The crustal end-member can be constrained by the lowest  $\epsilon Hf_{(1500 \text{ Ma})}$  value (~0) and the highest  $\delta^{18}$ O value (~10), and conversely the mantle-like end-member can be constrained by the highest  $\epsilon Hf_{(1500 \text{ Ma})}$  value (~8.3) and the lowest  $\delta^{18}$ O value (equivalent to the mantle value at ~5.3). For the crustal end-member a composition similar to that of young TIB crust is used (Figure 5.7); this corresponds in age to the 'normal deep crust' component advocated by Andersen et al. (2001, 2002b, 2009b). The  $\epsilon$ Hf of this crustal end-member is similar to a metagreywacke unit from the Idefjorden terrane (Figure 5.7), indicating that material with an appropriate age, Hf signature and sedimentary nature, does exist within the region. A  $\delta^{18}$ O value of 14 is used for the crustal component, and is based on an estimated average value for sedimentary rocks (Simon & Lécuyer 2005). The mantle end-member uses  $\epsilon$ Hf and  $\delta^{18}$ O values appropriate for depleted mantle at 1500 Ma.

Figure 5.8.  $\epsilon$ Hf<sub>(1500 Ma)</sub> versus  $\delta^{18}$ O VSMOW<sub>(zircon)</sub> for zircons of this study. Bulk-mixing curves and mantle and crustal end-members are discussed in the text. Symbols as in figure 5.5.

The use of either AFC or bulk-mixing modelling will result in similar mixing curves, but with different proportions of end-members (Kemp et al. 2007). In this study a simple two-component mixing model was employed, since Hf or O do not correlate with indices of differentiation (e.g.

SiO<sub>2</sub>; figures 5.5 and 5.6), as would be expected with an AFC process. Since the oxygen content is assumed to be similar in mantle and crustal rocks, the shape of the mixing curves depends on the Hf concentration of the end-members. The two curves shown (Figure 5.8) use depleted mantle (0.199ppm; Salters & Stracke, 2004) or lower crustal (1.9ppm; Rudnick & Gao 2003) values for the mantle end-member, combined with an upper crustal value (5.3ppm; Rudnick & Gao 2003) for the crustal end-member. Using depleted mantle combined with upper crustal values is compatible with a source contamination model; whereas using lower crust combined with upper crust values is compatible with a crustal contamination model. The data fall between the two curves, suggesting (assuming that the end-members are appropriate) that mixing is not limited to contamination in the mantle region, but has involved crustal input higher in the magmatic plumbing system. Alternative values could be chosen iteratively to fit the data; however, for any curve that falls through the data and uses the same end-member values, the mixing proportions will be similar. The Hf-O mixing curves indicate that 10-50% of the crustal component is required.

#### 5.5.5 Processes of continental recycling

Addition of a crustal component to mantle-derived magmas can be achieved by a number of processes. As discussed previously, the  $\delta^{18}O$  signature is too high to be compatible with contamination in the mantle via subducted high- $\delta^{18}O$  material. This is based on the assumption however, that the mantle is homogeneous in  $\delta^{18}O$ . Although this is normally the case (e.g. Valley et al. 1998), there are some examples where enrichment via mantle processes has lead to an increase in  $\delta^{18}O$  recorded in magma suites. In mantle domains enriched by subducted sediment (i.e. EM2),  $\delta^{18}O$  in olivine is increased from 5.2 to 5.7 (Workman et al. 2008); this is modeled as 2-3% sediment input. In the Banda arc,  $\delta^{18}O_{zircon}$  values are ~5.5 to 6.5 ‰ (Vroon et al. 2001), with the increase from the mantle value being related to 1-5% subducted sediment input. In settings where the subducted slab itself is postulated to have had an input to arc magmatism,  $\delta^{18}O_{melt}$  values reach ~8 ‰ (Setouchi belt, Japan; Bindeman et al. 2005). In all of these examples, the enrichment in  $\delta^{18}O$  is much smaller than that recorded in the Telemarkian rocks (up to  $\delta^{18}O_{zircon} \sim 10$  ‰), suggesting processes additional to mantle recycling are required.

In Kamchatka, arc basalts across the region have high- $\bar{\delta}^{18}$ O (up to 8.5‰  $\bar{\delta}^{18}$ O<sub>melt).</sub> The occurrence of these high- $\bar{\delta}^{18}$ O basalts is accounted for by one or more of three processes: 1) crustal contamination of mantle-like magmas with high- $\bar{\delta}^{18}$ O (~10‰) sediments in the lower or middle crust, 2) addition of high- $\bar{\delta}^{18}$ O (~10-20‰) slab fluids into the magma generation zone, or 3) parental basalts were derived by melting of thickened lower crust that already had high- $\bar{\delta}^{18}$ O (~6.5-7.2‰) (Bindeman et al. 2004). These processes can also be applied to this study; slab-fluid addition would require excessive amounts of fluids (Bindeman et al. 2004), and the  $\epsilon$ Hf of this component is likely to not have been evolved enough, since the subducting ocean crust will have been relatively young. Further to this, Hf has variably conservative behaviour; some studies have shown that it can be

mobilized in slab fluids (Woodhead et al. 2001; Barry et al. 2006), whereas others recorded immobile behavior (Pearce et al. 1999). Crustal assimilation is not advocated in the Kamtchatkan example because of energy conservation considerations (Bindeman et al. 2004). However, high amounts of assimilant are advocated in the Lachlan orogen (Kemp et al. 2007). In the Telemarkian rocks up to 50% assimilant is required using the proposed end-members, and is achievable according to the model of Kemp et al. (2007). Melting of an older high- $\delta^{18}$ O source is advocated for the Kamchatkan arc basalts, with this source being volcanic material such as high- $\delta^{18}$ O hydrated metabasalt (Bindeman et al. 2004); the high- $\delta^{18}$ O values are derived from deep-seated enrichment by slab fluids, or by low-temperature alteration followed by burial by tectonic and magmatic processes. For the Telemarkian magmatism, both crustal assimilation and melting of older high- $\delta^{18}$ O crust are concluded to be possible processes.

Discriminating between the different processes requires examining evidence outside of the zircon data. For the Telemarkian rocks, a variety of evidence points to input of the crustal component occurring within the parent magma source zone: 1) the lack of zircon inheritance is suggestive of introduction in the lower crust where magmatic temperatures are higher, and where zircon-free material is more likely to reside; 2) the geochemistry of the suite points to extensive fractional crystallisation of mafic parent magmas without crustal assimilation during differentiation; 3) data on zircon core-rim pairs are lacking, but repeat analyses on the same grains, whether on the same growth zone, or on different growth zones, are generally within analytical uncertainty of each other, suggesting that the crustal component was not introduced during the later stages of zircon crystallization; 4) a granitic sample with the most mantle-like values suggests that a degree of closed-system differentiation was able to occur; 5) Hf and O do not correlate with indices of differentiation (SiO<sub>2</sub>; Figures 5.5 and 5.6), as would be expected with an AFC process; 6) no definitively older metasedimentary rocks are found outcropping within the region, either as outcrop or as enclaves within the magmatic rocks. All of the evidence above is compatible with a setting in which the crustal component is mixed with depleted mantle or young mantle-derived material, in a lower crustal melting region, similar to the deep hot crustal zone setting (Annen et al. 2006), advocated in the Lachlan orogen (Kemp et al. 2007), or the Melting Assimilation Storage and Homogenisation (MASH) zone, advocated in the Andean arc (Hildreth & Moorbath 1988).

Establishing how a high- $\delta^{18}$ O source resided in the lower crust prior to Telemarkian arc magmatism is speculative. Possible processes could include burial of volcano-sedimentary rocks during repeated opening and closing of back-arc and fore-arc basins during tectonic switching (i.e. repeated compression and extension; Collins 2002) in an accretionary orogen; such a process is responsible for granite formation and continental growth in the Lachlan orogen (Kemp et al. 2007; Kemp et al. 2009). Another process is underthrusting and underplating of subducted oceanic crust and overlying sediments to the lower crust during preceding subduction stages; such a process is advocated as a way of inputting high- $\delta^{18}$ O sources to the melt region of the Sierra Nevada batholith (Lackey et al. 2005). Tectonic burial of a crustal component would possibly lead to localised variation in radiogenic isotope signatures; based on previous isotopic constraints, the existence of an older crustal component at depth is widespread beneath SW Fennoscandia. Another process described previously is enrichment of mafic lower crust by slab fluids during previous periods of subduction (Bindeman et al. 2004); whether this can occur to the extent required in the Telemarkian example is yet to be constrained, as no such examples exist in the literature.

The Suldal arc is suggested to be built on attenuated continental crust (see Chapter 4), such crust may be relatively immature in composition (i.e. mafic), and comprise low-temperature altered material in its upper portions; thus, building a continental arc on such crust may involve mobilisation of older high- $\delta^{18}$ O material. Further evidence is required to establish how exactly a high- $\delta^{18}$ O source had an input to the Telemarkian arc magmatism. Repeated episodes of compression/extension in a retreating accretionary orogen is likely to result in burial of high- $\delta^{18}$ O material; stretching of such crust into attenuated margins and continental ribbons is likely to produce widespread domains with possible high- $\delta^{18}$ O signatures. Thus, retreating accretionary orogens provide a setting where assimilation of older sedimentary material may be prone to occur. Irrespective of the exact mechanism for producing a high- $\delta^{18}$ O source, it is the mixing of this source in the melt generation zone that can be gleaned from the available data. By mixing in the source region, any characteristic geochemical signature that the high- $\delta^{18}$ O source may have is homogenized with a mantle-derived subduction-zone signature (i.e. in a MASH zone). Bulk-mixing in this MASH zone is heterogeneous, such that daughter magmas can exhibit variably enriched Hf and O isotope signatures (Figure 5.5 and 5.6). The high- $\delta^{18}$ O source could have included zirconbearing felsic material, but in this case the melt generation zone must have been hot and zirconundersaturated such that zircon was dissolved; more likely is that the high- $\delta^{18}$ O source was dominantly mafic, and comprised hydrated metabasalt as advocated for Kamchatkan arc magmas (Bindeman et al. 2004).

## 5.6 Conclusions

The Hf-O data in this study indicate that Telemarkian magmatism involved significant recycling of previously formed continental crust, with bulk-mixing calculations indicating 10-50% involvement of a component that has an average model age of ~2.15 Ga. This continental material was recycled within the crust (intracrustal recycling), comprised sedimentary material, and was mixed with mantle-derived material in the lower crust in a MASH zone (Hildreth and Moorbath 1988). The data do not exclude the existence of the 'normal deep crust' component of Andersen et al. (2001; 2004a, 2009b). It is suggested that the existence of older crust residing at depth in the Telemarkia terrane, is due to the fact Telemarkian arc magmatism was built upon crust that comprised Gothian-age

(>1600 Ma) sedimentary material. The continental building of Telemarkian and Gothian age crust occurred in a retreating accretionary orogen, which likely featured tectonic burial of sedimentary material, addition of mantle-derived melts to arc magmatism, and mobilization of older crustal material in melt generation zones. A modern analogue for this is the southwestern Pacific, which comprises oceanic and continental arcs at varying levels of maturity, which feature varying amounts of older ensiliac crust, but generally all include continental growth via juvenile mantle addition.

# Geochemical and Hf-O constraints on the petrogenesis of earlyto late-Sveconorwegian magmatism in S. Norway

Aim – In light of the new U-Pb ages for Sveconorwegian magmatism (see Chapter 3), the petrogenesis and tectonic setting of the different magmatic suites in southern Norway is discussed, basing observations on new in-situ Hf and oxygen isotope data combined with whole-rock geochemistry.

## 6.1 Introduction

During the Sveconorwegian orogeny, southern Norway was intruded by voluminous suites of granite *sensu lato*; these include suites of both I- and A-type affinity, with the latter including an Anorthosite-Mangerite-Charnockite (AMC) body. The abundance of large anorthosite massifs such as these is a unique feature of the middle Proterozoic. The origin of A-type granites, including Rapakivi-type suites which are commonly associated with AMC suites, is an ongoing matter of debate within igneous petrology (e.g. Martin 2006); understanding the petrogenesis of these magma series can inform us about processes of crustal formation and differentiation. Several processes are favoured for the genesis of A-type granites, including melting of granulitic refractory crust (Collins 1982; Clemens 1986; Whalen et al. 1987), melting of tonalitic crust (Anderson 1983; Creaser 1991; Patiño Douce 1997), and derivation from mafic crust (Frost & Frost 1997; Anderson et al. 2003). Recent studies using the accessory mineral zircon have constrained mixed mantle and crustal sources for both I and A-type granites (e.g. Peck et al. 2004; Kemp et al. 2006; Appleby et al. 2009; Be'eri Shlevin et al. 2009).

In southern Norway, four main suites of magmatism occurred around the period of the Sveconorwegian orogeny (1050-920 Ma). These are the Feda suite (I-type) at ~1050 Ma (Bingen et al. 1993; Bingen & van Breemen 1998), the Fennefoss suite at ~1035 Ma (Bingen & van Breemen 1998), the A-type Hornblende-Biotite-Granite (HBG) suite at 970-930 Ma (Andersen et al. 2002a, 2007a; Vander Auwera et al. 2003), and the Rogaland AMC suite at ~930 Ma (Schärer et al. 1996). Peak crustal thickening related to continent-continent collision occurred at ~1035 Ma (Bingen et al. 2008c), such that the Feda and Fennefoss suite are considered to be early- to syn-collisional suites, and the HBG and AMC suites are considered to be post-collisional. This study (see Chapter 3) has shown that undeformed granites normally grouped under the HBG suite are as old as 1047 Ma, and therefore pre-collisional in age, and also that deformed porphyritic granitoids (e.g. Feda suite) can be extended in their age range back to 1069 Ma. The emplacement of the HBG suite, although considered to be post-collisional, is controlled by orogenic structures (Duchesne et al. 1999; Bolle et al. 2003b); the suite intruded during phases of crustal doming that is related to the gravitational collapse of the Sveconorwegian orogen (Andréasson and Rodhe 1994; Romer 1996; Bingen et al.
2006). As a consequence of their different geodynamic setting, the petrogenesis of different suites is typically discussed separately.

C) Map of southern Norway showing the location of Sveconorwegian granitoid suites (modified from Bingen et al. 2005b; Vander Auwera et al. 2008; Slagstad et al. 2008). Ha = Hardangervidda Sector, Su = Suldal Sector, RVA = Rogaland Vest-Agder Sector, TIB = Transcandinavian Igneous Belt, MUSZ = Mandal-Ustaoset Shear Zone, KPSZ = Kristiansand-Porsgrunn Shear Zone, SSSZ = Saggrenda Sokna Shear Zone, VSZ = Vardefjell Shear Zone, ØBZ = Østfold Marstrand Boundary Zone, SFDZ = Sveconorwegian Frontal Deformation Zone, PZ = Protogine Zone. Grid co-ordinates are UTM zone 32V.

# 6.2 Previous studies

The HBG suite is defined as a ferro-potassic A-type suite (Vander Auwera et al. 2003), and is ferroan, metaluminous to weakly peraluminous, and features enriched incompatible elements as well as enriched large ion lithophile elements (LILE). Vander Auwera et al. (2003) showed that the HBG suite defines a differentiation trend from 50 to 77% SiO<sub>2</sub>; this trend is interpreted to represent extreme fractional crystallisation from basaltic parent magmas. Such parental basaltic parent magmas are postulated to be partial melts of a hydrous mafic and potassic source lying in the

lithospheric upper mantle, or the mafic lower crust derived from it (Vander Auwera et al. 2003). Differentiation via fractional crystallisation without assimilation is corroborated by data from the Lyngdal-Tranevag Suite (Bogaerts et al. 2003). Analysing natural and experimental data, and using trace element modeling, Vander Auwera et al. (2008) showed that both 73% fractional crystallization of an amphibole-bearing gabbroic cumulate subtracted from the parent mafic composition, and 30% non-modal batch melting of an amphibolitic source equivalent in composition to the mafic facies, produce a monzodioritic liquid that is appropriate to be a parent magma to the HBG suite.

Bogaerts et al. (2006) conducted crystallisation experiments on members of the Lyngdal Suite; comparison with natural data suggest crystallisation of a monzodioritic parent at 2-5 Kbar, with 5-6 wt% water and oxygen fugacity of NNO to NNO+1. An oxygen fugacity above NNO is also indicated by the assemblage magnetite+quartz+titanite (Vander Auwera et al. 2003). The high crystallisation temperature and water content of the Lyngdal Suite are suggested to be too high for primary magmas produced by partial melting of the crust (Bogaerts et al. 2006), with fractionation from mafic magmas being more likely. Using geothermobarometers (hornblende-plagioclase and Al-in-hornblende), crystallisation pressures are estimated at 1.3 to 2.7 Kbar for members of the HBG suite (Vander Auwera et al. 2003). Given the 5-6 wt% H<sub>2</sub>O content for the Lyngdal granodiorite (Bogaerts et al. 2006), the monzodioritic parent is calculated to have been 4.05 to 4.85 wt% H<sub>2</sub>O, and the amphibolitic source for this parent to have been 1.51 to 1.74 wt% H<sub>2</sub>O (Vander Auwera et al. 2008).

Andersen et al. (2001) group post-collisional granitoids in Telemarkia into three groups based on isotopic and trace element compositions; Group 1 (normal-Sr) granites have >150 ppm Sr,  ${}^{87}$ Rb/ ${}^{86}$ SR <5, Sri<sub>930Ma</sub> <0.710 and  $\epsilon$ Nd <0; Group 2 (low-Sr) have <150 ppm Sr,  ${}^{87}$ Rb/ ${}^{86}$ SR >5, Sri<sub>930Ma</sub> >0.710 and  $\epsilon$ Nd <0; Group 3 comprises one granite from the south of the Telemark Sector that has Sri<sub>930Ma</sub> <0.710 and  $\epsilon$ Nd >0. Most of the HBG suite falls into Group 1, whereas plutons in the north of the Telemark Sector fall into Group 2.

The gneissic country rocks exposed in Rogaland have too high a <sup>87</sup>Sr/<sup>86</sup>Sr ratio to be involved in the petrogenesis of Group 1 HBG granitoids (Bogaerts et al. 2003; Vander Auwera et al. 2003). The restricted Sr range also suggests (but is not restricted to) contamination by a Rb-depleted (i.e. granulitic lower crust) source (Vander Auwera et al. 2003). The absence of a correlation between SiO<sub>2</sub> and Sr<sub>i</sub> or  $\epsilon$ Nd suggests assimilation is not controlling the isotope signatures of the HBG suite (Bogaerts et al. 2003).

Andersen et al. (2001) postulate various crustal end-members found within southern Norway; 'CA' is moderately LILE-enriched deep crust with a  $T_{DM}$  of 1.9 Ga and has a composition similar to

'upper continental crust'; 'CB' also has a  $T_{DM}$  of 1.9 Ga, is more LILE-enriched and is equivalent to metasedimentary gneisses in the Bamble terrane; 'CC' has a  $T_{DM}$  of 1.7 Ga with highly radiogenic <sup>87</sup>Sr/<sup>86</sup>Sr. Bolle et al. (2003a) postulate two different crustal end-members for Sr-Nd mixing calculations, 'C1' has a  $T_{DM}$  of 1.8 Ga and is LILE-enriched, and 'C2' has a  $T_{DM}$  of 1.9 Ga and is moderately LILE-enriched. Mixing between a depleted mantle component and CA/C2 (moderately LILE-enriched, normal-Sr, 1.7-1.9 Ga in age) crustal end-member can produce the isotope signature of Group 1 granites in Telemark and Rogaland with 30-70% of the crustal end-member. Binary mixing between these two end-members requires 20-40% crustal contamination to produce the composition of the monzodioritic parent liquid to the HBG Suite (Vander Auwera et al. 2008). This amount of contamination is suggested to be unrealistic, but can be lowered to 10-20% by using higher Sr and Nd contents (Vander Auwera et al. 2008). Group 2 granites require the CC (highly radiogenic <sup>87</sup>Sr/<sup>86</sup>Sr) end-member to be involved. Whereas the isotope compositions of Nd and Sr in the crustal and mantle end-members can be related to non-element selective bulk-mixing processes, the lead-isotope systematics require element selective processes such as fluid-exchange (Andersen et al. 2001).

Andersen et al. (2002b, 2007b, 2009b) and Andersen & Griffin (2004) present in-situ hafnium zircon data for various Sveconorwegian granitoids from across southern Norway. The Hf data corroborate with whole-rock Nd data, in terms of the relative amounts of mantle and older crust required in bulk-mixing calculations. Scarce inherited zircon signatures (see Figure 6.12) are inferred by these authors to confirm the presence of older Palaeoproterozoic crust at depth. However, as discussed by Liégeois and Stern (2010), inherited zircons do not confirm the existence of older crust; they only confirm that older zircons were available for assimilation. The most radiogenic (but non-outlying and non-inherited) Hf isotope composition of the Sveconorwegian granites requires involvement from a source with EHf<sub>950Ma</sub> -4, which approximates to a model age of 1950 Ma (2-stage using Lu/Hf 0.015; Andersen et al. 2002b). Hf data on gneisses in central Telemark and younger granitoids suggest depleted mantle input to magmatism at ~1.2 Ga (Andersen et al. 2007b), that later formed a source involved in the Sveconorwegian magmatism (Andersen et al. 2009b). The range in  $\varepsilon$ Hf for individual plutons reaches >8 epsilon units; this is suggested by Andersen et al. (2009b) to be incompatible with closed-system differentiation of a homogeneous parental magma, however, closed-system differentiation from a heterogeneous source is not considered by the authors.

Andersen et al. (2002b) stated that mid-Proterozoic (i.e. 1.5-1.6 Ga) calc-alkaline protoliths are unlikely to have been a source for the Sveconorwegian granitoids in Telemarkia, because no such rocks exist in the region. However, this has recently been shown to not be the case, in fact widespread exposed crust in Telemarkia is constructed of calc-alkaline Telemarkian (1.52-1.48 Ga) gneiss (Bingen et al. 2005b, see Chapters 2-5).

The Rogaland AMC suite involved fractional crystallisation of a mafic anhydrous parent magma under low oxygen fugacity (Vander Auwera & Longhi 1994; Vander Auwera et al. 1998; Longhi et al. 1999), with anorthosite bodies forming by diapiric rise of plagioclase accumulations (Emslie 1985; Longhi et al. 1993). Fractional crystallization of the parent magmas involved crustal contamination, with different magma batches undergoing varying degrees of contamination (Bolle et al. 2003a); the crustal contaminant is represented by moderately to strongly-LILE enriched gneisses 1.5-1.9 Ga in age. Re-Os isotope data from the AMC suite suggest formation by melting of a mafic lower crust that is 1400-1550 Ma in age (Schiellerup et al. 2000).

The Feda suite is high-K, calc-alkaline, metaluminous, and displays characteristics typical of continental arc granites (Bingen & van Breemen 1998). It has been modelled via bulk-mixing of ultra-potassic-mantle and crustal components (Bingen et al. 1993). Andersen et al. (2001) showed that 20-35% crustal contamination using CA/C2 and depleted mantle end-members can produce the required isotopic compositions. Although the fields for Feda granitoids and Group 1 granites overlap in Nd and Sr space, lead isotope data indicate that the Group 1 granites cannot be formed purely by remelting of Feda granitoids (Andersen et al. 2001).

Figure 6.2. Geological map with sample localities of this study. (see Figure 6.1 for references)

The Fennefoss suite comprises similar augen gneisses to that of the Feda suite, but with a geochemical signature transitional between A-type and subduction-zone related; this signature is interpreted to represent the last vestiges of a subduction regime (Bingen & van Breemen 1998).

# 6.3 Analytical Methods

Whole-rock geochemistry was conducted using methods outlined in Chapter 4; hafnium and oxygen isotope analyses were conducted using methods outlined in Chapter 5.

# 6.4 Petrography and geochemistry

#### 6.4.1 The HBG suite

Samples of the HBG suite in this present study come from the Storlivatnet intrusive complex in the Suldal Sector and from the Sjelset and Søredalen intrusive complexes in the RVA Sector (Figure 6.2). The Storlivatnet complex contains various units, both deformed and undeformed, with ages at  $1021 \pm 8$  Ma,  $1039 \pm 15$  and  $1069 \pm 9$  Ma (see Chapter 3). The dominant lithology is a coarsegrained porphyritic granite comprising K-feldspar, altered plagioclase, quartz and biotite; hornblende is present in some units, and titanite is often intergrown with biotite. The Søredalen intrusive complex contains medium to coarse grained undeformed and deformed granitic units, with ages at  $991 \pm 35$  and  $1003 \pm 43$  Ma. The granites are composed of K-feldspar, plagioclase and quartz, with minor biotite and muscovite, and variable amounts of garnet; up to 20% garnet occurs where the granites contain inclusions and schlieren of pelite. The Sjelset intrusive complex complex complex on a ~990 Ma units; the latter is sampled in this study. The sampled granite is dated at  $993 \pm 16$  Ma, and comprises K-feldpar, quartz, altered plagioclase, biotite and muscovite.

The geochemistry of the HBG granites is compared with other members of this suite in figures 6.3 to 6.6. The HBG granites are metaluminous to weakly peraluminous, ferroan (except one sample), and calc-alkalic to alkali-calcic (Figure 6.3). In their major and trace element contents the samples of this study mostly overlap those of previous studies (Figures 6.4 & 6.5); SiO<sub>2</sub> content ranges from 68.7 to 76.4 %. The HBG suite forms bell-shaped trends in some elements (e.g. Ba, Nb and Zr), positive trends in others (e.g. Rb), and negative trends in others (e.g. Sr, V); inflections in these trends occur at ~60-65% SiO<sub>2</sub>. On the primitive-mantle normalised plot (Figure 6.7), the HBG suite exhibits relative depletions in Ba, Nb, Sr, P, Eu and Ti. These can be related to fractionation of feldspar (Ba, Sr and Eu), apatite (P) and titanite/Fe-Ti oxides (Ti). The depletion in Nb is typical of subduction-related magmas, suggesting the HBG granites formed by remelting or fractionation of subduction-related parent magma. The HBG granites exhibit enrichment in LILE and HSFE, and positive LILE/HFSE and LREE/HREE ratios.

#### 6.4.2 The Feda suite

The Feda suite refers to ~1050 to ~1020 Ma megacrystic (alkali-feldspar) granitoids that form the Sirdal Zone; the Sirdal zone is defined as the zone separating the Suldal sector to the northeast from the Rogaland sector to the southwest (Slagstad et al. 2008). The Sirdal zone comprises large

Figure 6.3. Geochemical classification diagrams for granitoid suites in southern Norway. Data for Lategranite, leucogranite and Feda granitoid from this study; HBG Suite from Auwera et al. (2003); Feda Suite and Fennefoss Suite from Bingen et al. (1993). ASI (aluminium saturation index), FeOt(FeOt+MgO) (i.e. Fe\*) and Na2O+K2O-CaO (i.e. MALI) from Frost et al. (2001).

volumes of megacrystic granitoid gneiss, leucocratic granite-pegmatite, and smaller volumes of medium-grained biotite-granite. The term 'Feda' Suite originally referred to ~1050 Ma augen gneisses outcropping to the south of the RVA Sector (Bingen et al. 1993; Bingen & van Breemen 1998), and is retained here for all porphyritic granitoids of this age that outcrop in the Sirdal Zone. The Feda granitoids are undeformed to moderately deformed, but folded by large, open folds with wavelengths of up to several kilometres (Slagstad & Marker 2009, pers. comm.). Samples within this study are dated at  $1019 \pm 10$ ,  $1027 \pm 24$ ,  $1043 \pm 6$ , and  $1046 \pm 3$  Ma (Slagstad & Marker 2009, unpublished data). The granitoids are granodioritic to granitic, and typically exhibit large (1-2cm) K-feldspar phenocrysts, sometimes red in colour. The matrix is composed of altered plagioclase, quartz and K-feldspar, with biotite in all samples, and hornblende, titanite and epidote being minor minerals in some units.

Previous geochemical data from the Feda suite (Bingen et al. 1993) is shown for comparison with the new data in figures 6.3 to 6.6. The Feda suite ranges from quartz monzodiorite and granodiorite to granite, is metaluminous to weakly peraluminous, and alkali-calcic (Figure 6.3). On the Fe\* classification (FeO<sup>t</sup>/(FeO<sup>t</sup>+MgO; Frost et al. 2001) the previous Feda data exhibit a magnesian

trend; data from this study fall into two groups, one that overlaps the previous magnesian trend, and one that overlaps the ferroan HBG suite. In major and trace element contents the Feda suite exhibits trends that are similar to the previous Feda data; however some of the new data is different in that they overlap the HBG trends. The trends between the Feda and HBG suites are typically subparallel, but with varying contents of some elements. For example, in major element contents the Feda suite has lower TiO<sub>2</sub> and FeOt, and greater MgO and Al<sub>2</sub>O<sub>3</sub>; in trace element contents the Feda suite has lower Nb and Zr, greater Sr, and similar Ba and Rb (Figures 6.4 and 6.5). The Feda suite exhibits relative depletions in Nb, P, Eu and Ti (Figure 6.7); the depletions in P, Eu, and Ti are all to a lesser extent than in the HBG suite. The LILE are similarly enriched to that of the HBG suite, but the HFSE are less enriched. The LREE enrichment relative to HREE enrichment is also greater in the Feda Suite (La/Y; Figure 6.6).

Figure 6.5. Harker diagrams for selected trace elements. Symbols as in figure 6.3 except for the HBG suite which is plotted at black diamonds.

Figure 6.6. SiO<sub>2</sub> versus Al/Ga, Total REE contents, La/Yb and Eu\*/Eu. Eu\* = Eu/( $\sqrt{\text{Sm}*\sqrt{\text{Gd.}}}$ ) Symbols as in figure 6.4 except for the Feda Suite which is plotted as small grey-filled circles.

#### 6.4.3 Leucogranites

Leucocratic granite and pegmatite are found within the Sirdal zone, and are characterised by gradual transitions, on a several-meter scale, between coarse-grained granite and pegmatite. Inclusions of fine-grained migmatitic paragneiss are found abundantly in parts of the leucocratic granite-pegmatite. Samples are dated at  $1021 \pm 61$ ,  $1025 \pm 25$ , and  $1045 \pm 13$  Ma (Slagstad & Marker 2009, unpublished data). The sampled leucogranites are typically medium-grained biotite granite, comprising K-feldspar, quartz, altered plagioclase and biotite. Some areas are rich in inclusions of amphibolite or gneiss; within these, opaque minerals, titanite and zircon are more abundant, sometime forming schlieren.

The leucogranites straddle the boundary between metaluminous and peraluminous, are variably ferroan/magnesian and calc-alkalic to alkali-calcic (Figure 6.3). In major and trace element contents the leucogranites roughly overlap the evolved members of the HBG suite (Figures 6.4 to 6.6). In the primitive mantle normalised plot (Figure 6.7) the leucogranites exhibit depletions in Ba, Nb, Sr, P, Eu and Ti; the depletions are similar in extent to those of the HBG suite. The LILE/HFSE and LREE/HREE enrichment in the leucogranites is similar to that of the Feda Suite (Figures 6.6 to 6.7).

Figure 6.7. Primitive mantle (Sun & McDonough 1989) normalised plots comparing the HBG, Feda and Leucogranite suites.

### 6.4.4 Zircon saturation temperature

Figure 6.8 shows zirconium content plotted against M ((Na+K+2Ca)/Al\*Si)) for the samples in this study, along with zircon saturation isotherms from Watson & Harrison (1983). The magnesian members of the Feda suite fall close to the 800°C isotherm, whereas the ferroan members extend to higher temperatures similar to those of the HBG suite. The leucogranites have relatively low temperatures (<810°C).

Figure 6.8. M ((Na+K+2Ca)/(Al\*Si)) versus Zr ppm for granite suites of this study, isotherms are zircon saturation temperature (calculated from Watson & Harrison 1983).

# 6.5 Results - Hf isotopes

Hf isotopes were measured in 12 granitoids from across the study area (Figure 6.9). Two of these samples (MM2230 and MM26297) are from the leucogranite belt within the Sirdal Zone (Figure 6.2), and include inherited zircons that are ~1500 Ma in age; the  $\epsilon$ Hf of these inherited zircons is between +7.51 and 12.74). Disregarding the inherited zircons, the total range in  $\epsilon$ Hf across all samples (6.5 epsilon units) is fairly narrow considering the number of samples. The mean of each sample varies from  $\epsilon$ Hf -0.78 to +2.57. Within each sample the range in  $\epsilon$ Hf is limited, with the MSWD being between 0.03 and 2.3 for 10 out of 11 samples. The sample with a higher MSWD (MM26302) features two analyses that have higher  $\epsilon$ Hf that are out of the range of the entire suite. This is the only sample with a convincing degree of geological heterogeneity; analytical uncertainty can explain the heterogeneity within the other samples. Two stage model ages (T<sub>DMC</sub>) range from 1474 Ma to 1887 Ma.

Figure 6.9. Results of in-situ Hf analyses;  $\epsilon$ Hf<sub>(initial)</sub> is plotted against arbitary units. For each sample the weighted mean and 2s.e. are shown as a black solid line and block dotted lines respectively. From MM26297, only ~1500 Ma inherited zircons were analysed for Hf; U-Pb analyses reveal a ~1045 Ma population of magmatic zircons.

# 6.6 Results - Oxygen isotopes

Oxygen isotope data was determined on a subset of six samples (Figure 6.10). The total range in  $\delta^{18}$ O is from +4.66 to +12.09‰. Five of the samples have means (+5.74 to +7.07‰) that are slightly above the mantle value (5.3 ± 0.3‰), and one sample (MM26306) has values that are much higher (mean = +11.63 ‰). The range in each sample is variable; in three samples (MM26306, ROG641 and SA3-01) the range is within analytical uncertainty (MSWD = 0.69 to 1.7), and in the other three samples (MM2247, MM26032 and ROG80) the range likely represents geological heterogeneity (MSWD = 3.2 to 8.1).

Figure 6.10. Results of in-situ oxygen analyses;  $\delta^{18}$ O VSMOW <sub>(zircon)</sub> plotted against arbitary units. For each sample the weighted mean and 2s.e. are shown as a black solid line and block dotted lines respectively. Mantle zircon =  $\delta^{18}$ O 5.3 ± 0.3 ‰ (Valley et al. 1998).

# 6.7 Discussion

#### 6.7.1 Hf-O constraints on magma source

Figure 6.11 shows  $\epsilon$ Hf versus time for the granitoids of this study along with published data from the region. The  $\epsilon$ Hf of the Feda suite is remarkably similar to that of the HBG Suite; there is no temporal change in  $\epsilon$ Hf either, with granitoids across the Sveconorwegian period all having similar values. The range in  $\epsilon$ Hf for an individual sample in this study was typically smaller than that measured in previous studies (Andersen et al. 2002a, 2007b, 2009b); whether this is due to real geological variation or an analytical effect is difficult to constrain, since previous studies include a greater number of analyses per sample.

The Sveconorwegian granitoids intrude 1.5-1.6 Ga crust that is calc-alkaline and rather juvenile in nature (Chapter 5; Andersen et al. 2002a), the evolution of this crust is shown in Figure 6.11; also shown is the evolution of ~1.7-1.9 Ga Transcandinavian Igneous Belt (TIB) crust. The Sveconorwegian granitoids largely overlap with the 1.5-1.6 Ga crust, suggesting that remelting of 1.5-1.6 Ga crust to produce the younger granitoids is compatible with the Hf isotope data. Outliers in the previously published data that have low  $\varepsilon$ Hf (see Figure 6.11) have been used as evidence for an older >1.7 Ga component to be involved in the petrogenesis of the late-Sveconorwegian granitoids (Andersen et al. 2002b; 2007b; 2009b). These potentially inherited zircons are small in number, they lack U-Pb data in some cases, and in others the U-Pb data is not discussed in terms of discordance/metamorphic disturbance; the evidence for a >1.7 Ga component based on these zircons is therefore unpersuasive.

The mantle is a remarkably homogeneous oxygen isotope reservoir, with igneous zircons formed in equilibrium with the mantle having an average  $\delta^{18}$ O of 5.3 ± 0.3‰ (Valley et al. 1998). High

magmatic  $\delta^{18}$ O values (>6.5‰) are attributed to melting or assimilation of sediments, altered volcanics, or other supracrustal rocks affected by low-temperature alteration, whereas low magmatic  $\delta^{18}$ O values are attributed to incorporation of material that has undergone high temperature alteration (Valley et al. 2005). Oxygen isotopes can therefore be used to discriminate mantle recycling from intracrustal recycling.

Figure 6.11.  $\epsilon$ Hf<sub>(initial)</sub> versus intrusion age (Ma) for Sveconorwegian granitoids. The field for 1.5-1.6 Ga granitoids is based on data from Andersen et al. (2002b) and Chapter 5. The field for TIB (1.7-1.9 Ga) crust is based on data from Andersen et al. (2009a). The evolution of these fields uses an average crustal Lu/Hf value of 0.015. Depleted mantle (DM) is based on Griffin et al. (2000), and CHUR uses values of Bouvier et al. (2008). Error bars represent 2s.d. of the mean.

Oxygen isotopes are similar for both Feda suite granitoids (MM2247, MM26302, and ROG80) and HBG granitoids (ROG641, SA3-01). The average values are above the mantle range, suggesting a magmatic source with a high- $\delta^{18}$ O, such as weathered continental crust. The origin of the highest- $\delta^{18}$ O granitoid (MM26306) is discussed in section 6.7.5. In summary, the Hf-O isotope data suggest a similar source is likely for both ferroan and magnesian magmas, and for early- syn- and late-orogenic suites.

#### 6.7.2 Formation of silicic melts - magma mixing versus fractional crystallization

An origin for the HBG suite via fractional crystallisation has been advocated in various studies (Vander Auwera et al. 2003, 2008; Bogaerts et al. 2003, 2006). Andersen et al. (2009b) disagree with this model, instead, they suggest a model whereby silicic end-members have been formed by

crustal anatexis, and these have mixed with differentiated and contaminated mantle-derived mafic end-members. The bell-shaped trends observed in some trace element harker diagrams are pivotal to this debate (see Figure 6.12). Vander Auwera et al. (2003) suggest the bell-shape is due to a change in fractionating phases such that certain trace elements behave incompatibly during early fractional crystallisation, turning to compatible behavior during fractionation of more evolved magmas. A lack of magma-mixing between mafic and silicic end-members means that samples do not fall within the bell-shape. Andersen et al. (2009b) propose that mafic magmas have differentiated producing positive trends at low silica content, silicic melts are formed by partial melting of crustal rocks, and that the negative trend after ~55% SiO<sub>2</sub> is due to mixing between these silicic melts and the differentiated mafic melts. In this case, mixing should occur between silicic melts and mafic compositions at varying degrees of differentiation, such that a variety of mixing lines are produced (see Figure 6.12c); the lack of such mixing lines in the data is suggested by Andersen et al. (2009b) to reflect a lack of local homogenization. Andersen et al. (2009b) also point out that the HBG trend discussed by Vander Auwera et al. (2003, 2008) is made up of unimodal or bimodal clusters, and that individual plutons do not exhibit single differentiation trends (see Figure 6.12a).

Figure 6.12. A) SiO2 verus Zr for plutons within southwest Norway. Aseral, Handeland, Svofjell, Lyngdal, Holum, Rustfjellet, Red granite and Bessefjellet are members of HBG suite shown in figures 6.3 to 6.6 (from Vander Auwera et al. 2008 & Bogaerts et al. 2003); Storlivatnet and Søredalen are members of HBG suite from this study; other data points represent other individual plutons in the region (from Andersen et al. 2009b). B) evolution of the HBG trend via fractional crystallisation of a mafic parent magma (see text) C) evolution of the HBG trend via mixing between mafic parent magmas, and silicic melts derived from crustal anatexis. (see text for explanation of these models).

In response to these arguments it is worth pointing out that typical models for formation of granite plutons, involve segregation of felsic melts, collection of these melts into larger bodies, and buoyant uprise of these bodies via varying dyking/stoping mechanisms (e.g. Marsh 1992; Brown 1994; Petford et al. 2000). Therefore, mafic and intermediate compositions are often going to be located at

deeper crustal levels than that of the felsic plutons. The density contrast between mafic/intermediate and felsic melts means that even if all melts are mobilized, the felsic magmas will rise highest in the crust. Arguments against differentiation of felsic plutons from mafic magmas have often cited the argument of a lack of exposed mafic to intermediate crust (e.g. Haapala et al. 2005), however, these are hindered by the fact that exposure at the surface is typically constrained to a certain crustal level (normally upper-crustal). As pointed out by Vander Auwera et al. (2008), if the HBG suite was formed by fractionation of a lower crustal mafic parent magma, then the mafic residues are likely to still reside in the lower crust, or to have been returned to the mantle.

The trends in figure 6.12 are compatible with differentiation of a parent magma with ~57% SiO2 and ~800 ppm Zr, to more evolved composition with lower Zr. This parent magma is indicated by Bogaerts et al. (2003, 2006) to be a monozodioritic composition. Using experimental and natural data, Vander Auwera et al. (2008) show that this monzodiorite composition can be produced by both fractional crystallisation and partial melting of an amphibolitic source magma. The new data presented here overlap the previous HBG data, and do not help resolve the issue over which petrogenetic process is responsible. However, the petrogenetic model proposed later in this chapter advocates differentiation from mafic parent magmas, either by fractional crystallisation, partial melting or more likely by both processes; in so doing this the model does not contradict the experimental data or modelling of natural data, but also aims to account for the isotopic constraints that Andersen et al. (2001, 2002b, 2007b, 2009b) outline in their petrogenetic models.

#### 6.7.3 Geochemical constraints on magma source

For Sveconorwegian magmatism, Bingen et al. (1993) advocate a change in Fe\* over time, with early granitoids (Feda suite) having low Fe\*, late granitoids (HBG suite) being highest in Fe\*, and the Fennefoss suite falling in the middle. The data presented here shows that although the granitoids <1000 Ma are all ferroan (high Fe\*), early granitoids are both magnesian (low Fe\*) and ferroan; therefore the geochemistry is changing spatially and not just temporally. The ferroan samples have higher TiO<sub>2</sub>, FeO<sup>1</sup>, and incompatible elements (e.g. Nb, Zr, REE), lower MgO, Al<sub>2</sub>O<sub>3</sub> and Al/Ga, and greater depletion in Ba, Sr, P and Eu (Figures 6.4 to 6.7). These characteristics are all typical features of A-type granites (e.g. Whalen 1987; Collins 1982), and can be explained by a greater degree of plagioclase fractionation (which lowers Ba, Sr, Eu in residual melts), lesser degree of partial melting or melting of an enriched source (to account for the increase in incompatible elements). A-type granites form at higher temperatures than I-type granites (Collins 1982; Clemens et al. 1986). The difference between zircon saturation temperatures of the magnesian and ferroan granitoids (see Figure 6.8) is compatible with the ferroan members of the Feda suite being more closely related to A-type magma series.

Changes between the amount of plagioclase fractionation versus the amount of Fe-Ti oxide fractionation can be related to intensive parameters during melt generation. An increase in water content promotes the stability of plagioclase and reduces the stability of Fe-Ti oxides (Gaetani et al. 1993; Sisson & Grove 1993), an increase in oxygen fugacity has the same effect although to a lesser extent (Toplis & Carroll 1995; Feig et al. 2006; Hamada & Fuji 2008), and an increase in pressure has the reverse effect (Grove et al. 2003). Water content also has the effect of lowering the solidus, meaning that the degree of melting will be increased in hydrous conditions (Baker et al. 1994), as is consistent with the incompatible element contents. The importance of plagioclase fractionation for producing A-type magmas means they typically have anhydrous sources advocated. It could thus be inferred that the source conditions for the magnesian granites were hydrous and more oxidising, and for the ferroan granites were anhydrous and reducing. This is contradicted however by experiments on the parent to the Lyngdal granodiorite, suggesting crystallization at 2 to 4 Kbar from a magma with 5 to 6 % H<sub>2</sub>O at an fO<sub>2</sub> of NNO to NNO+1 (Bogaerts et al. 2006). Such oxidizing and hydrous conditions have been recognised in other A-type granites, and form a subset classified as oxidized A-type granites (Dall'Agnol et al. 1999; Dall'Agnol & Oliveira 2006); such granites typically contain >4 wt% H<sub>2</sub>O and can be derived from lower crustal igneous quartzo-feldspathic sources (Dall'Agnol & Oliveira 2006).

Trends for the Feda and HBG suites do not appear to converge at low silica contents, although this conclusion is hampered by the lack of mafic (<57% SiO<sub>2</sub>) compositions in the Feda suite. At  $\sim57\%$  SiO<sub>2</sub> the two trends are markedly different in major and trace element contents, therefore, the monzodiorite parent magma that evolved to form the HBG suite (Vander Auwera et al. 2008), is not suitable for forming the Feda suite. Thus, formation of these two suites may have involved either a different source magma, or different conditions during fractionation/melting of this source to produce different parent magmas.

The Hf-O isotope data, and previous Nd and Sr data (Bingen et al. 1993; Andersen et al. 2001), point to a similar source in terms of isotope signatures for both the Feda and HBG suites. The similarity in geochemical enrichment (see Figure 6.7), except for elements related to plagioclase/Fe-Ti oxide fractionation, is also striking. The negative Nb anomaly in both suites is suggestive of a source with a subduction-zone influence, as opposed to asthenospheric mantle which typically lacks a Nb anomaly (e.g. Thompson 1983; Fitton et al. 1997). Both whole-rock and isotope geochemistry point to a similar source for the HBG and Feda suites; thus, the influence of crystallisation conditions is advocated for the changes in geochemistry.

In the model of Vander Auwera et al. (2008), the monzodiorite parent magmas to the HBG suite contain 4.05-4.85 wt%  $H_2O$ , likely formed by partially melting of amphibolite with 1.5-1.7 wt%

 $H_2O$ , which originated by fractionation or partial melting of a lower crustal source with 0.34-0.85 wt%  $H_2O$ . The Feda suite source magmas likely contained a greater water content than this, so that Fe-Ti oxide relative to plagioclase stability was increased, therefore hindering iron enrichment and producing more magnesian compositions; and also producing greater degrees of partial melting. The greater water content in the Feda suite is compatible with their postulated supra-subduction zone origin (Bingen et al. 1993; Bingen & van Breemen 1998; Slagstad et al. 2008). Over time the Sveconorwegian magma suites become entirely ferroan, this temporal change can be related to a decrease in the water content of the magma sources over time. A temporal decrease in water content can be related to dehydration via successive melting and heating from magmatic underplating (Landenberger & Collins 1996). Since continent-continent collision occurred by 1035 Ma (Bingen et al. 2008c), any flux of water related to a postulated subduction zone will have been cut off by ~1035 Ma.

As noted previously, as well as the HBG suite being ferroan, some members of the Feda suite are also ferroan (including MM26306 - 1046±3 and ROG218 – 1027±24 Ma). Thus, an explanation of the ferroan and magnesian trends must allow for their contemporaneous formation (at least at a >1 Myr timescale). To account for this, a suggested model (Figure 6.13) involves: 1) melting of mafic lower crust to form parent magmas that evolve to magnesian Feda granitoids, 2) dehydration zones occurring above the melt generation zones, and 3) melting of the dehydrated lower crust for form parent magmas that evolve to ferroan Feda granitoids. This model is base on that proposed for the Triassic I and A-type granites of the Chaelundi Complex, Australia (Landenberger & Collins 1996). Generation and ascent of early formed magnesian magmas leaves the crust relatively anhydrous but not refractory (chemically depleted); this crust will stay anhydrous unless new hydrous mantle-derived arc magmas are intruded. Remelting of this refractory crust is only achievable at high temperatures (>900°C; Landenberger & Collins 1996); this can occur during prolonged periods of magma underplating, but may require thinning of the crust and heat from asthenospheric mantle (Zhao et al. 2008).

Two possibilities exist for the origin of the heterogeneity in water content in the Sveconorwegian lower crust, 1) that the lower crust was already low in water content prior to the Sveconorwegian orogeny, and that increased water content occurred when there was sufficient volatile flux from subduction, or 2) that the crust didn't have low water content prior to the Sveconorwegian orogeny, and that dehydration zones that sourced ferroan magmas were formed by continued heating and extraction of melts. Given that there is evidence for magmatic underplating and A-type magmatism prior to the Sveconorwegian orogeny, i.e. 1.2 Ga juvenile magmatism in Telemark (Andersen et al. 2007b), and 1.16 Ga charnockite intrusions in Rogaland Vest-Agder (Zhou et al. 1995), it is postulated that the crust was already low in water content prior to the Sveconorwegian orogeny.

Figure 6.13. Petrogenetic model for the formation of the Feda, HBG and AMC suites; see text for explanation. Modified from Vander Auwera et al. (2008).

### 6.7.4 Leucogranite formation

The leucogranites (MM2230 and MM26207) have Hf isotopic signatures similar to the HBG and Feda suite (Figure 6.10). The geochemistry of the samples is rather scattered, but in general the data fall on trends that overalp with the Feda suite (Figures 6.3 to 6.6). In the primitive mantle normalised diagram (Figure 6.7) the leucogranites have similar LILE and HFSE enrichments to that of the Feda suite; depletions in Ba, Sr, P, Eu and Ti fall between those of the Feda and HBG suite.

The leucogranite samples have higher silica content than the Feda suite, and are found spatially with Feda granitoids. For these reasons, it is hypothesised that the majority of the leucogranites represent highly differentiated members of the Feda suite.

#### 6.7.5 Continental recycling during Sveconorwegian magmatism

The Hf and oxygen isotopes point to a similar source for both magnesian and ferroan granitoids, and also for early-, syn- and late-Sveconorwegian suites. This source included a component that is substantially greater in age than the granitoids; average model ages fall in the region of 1700 to 1900 Ma. The  $\delta^{18}$ O data suggest that this older component comprised a high- $\delta^{18}$ O source, such as weathered sediments, thus, the magnatism involved recycling of continental material via intracrustal processes.

The Hf-O data can be produced by remelting of 1.5-1.6 Ga crust that has a high- $\delta^{18}$ O signature, however, previously determined whole-rock isotope and geochemical studies have shown that both a mantle and crustal component was involved in the petrogeneses of the early- and late-Sveconorwegian granitoids (Bingen et al. 1993; Vander Auwera et al. 2003; Bogaerts et al. 2003; Andersen et al. 2001). For example, Nd and Sr measured on late-Sveconorwegian granitoids in Rogaland, points to bulk mixing between 45-70% depleted mantle, and 30-55% of a crust component (the 'normal deep crust'; Andersen et al. 2001). To compare the new Hf-O data with previously published models, bulk-mixing calculations are discussed.

Figure 6.14 shows  $\epsilon$ Hf versus  $\delta^{18}$ O that is measured on the same zircons. Shown on this diagram is the range in Hf-O that ~1.5-1.6 Ga crust would have at 950 Ma (based on data presented in Chapter 5). C1 is a crustal component correlative in age with the 1.7-1.9 Ga deep crustal component of Andersen et al. (2001; 2007b; 2009b), and has a high- $\delta^{18}$ O of +12 compatible with a sedimentary origin. C2 is a crustal component that is equivalent in age to C1, but has a mafic  $\delta^{18}$ O signature; this component is therefore compatible with ancient underplated material. C3 is a crustal component that is young relative to the magmatism (i.e. <1200 Ma), and has high- $\delta^{18}$ O of +11; this component is compatible with an origin as young weathered sediments that have been derived from the Fennoscandian continent.

Since the oxygen content is assumed to be similar in mantle and crustal rocks, the shape of the mixing curves depends on the Hf concentration of the end-members. The curves shown use either depleted mantle (0.199ppm; Salters & Stracke 2004) or lower crustal (1.9ppm; Rudnick & Gao 2003) values for the mantle end-member, combined with an upper crustal value (5.3ppm; Rudnick & Gao 2003) for the crustal end-member. Using depleted mantle combined with upper crustal values is compatible with a source contamination model; whereas using lower crust combined with upper crust values is compatible with a crustal contamination model. The majority of the granitoids

in this study can be modelled with bulk-mixing between older crustal components that are variable in oxygen values (C1 and C2), with a depleted mantle contribution of 50-70%.

Figure 6.14.  $\epsilon$ Hf<sub>(950 Ma)</sub> versus  $\delta^{18}$ O VSMOW<sub>(zircon)</sub> that are measured in the same zircon domains. The grey dashed box represents average 1.5-1.6 Ga crust at 950 Ma, based on HF-O data in Chapter 5. Values for crust and mantle end-members are discussed in the text. Curves are derived from bulk-mixing calculations, with dashes marking 20% increments. The filled grey bar represents values for young altered ocean crust and overlying sediments. The grey unfilled boxes represent the total range in  $\epsilon$ Hf and  $\delta^{18}$ O for each sample. (Symbols as in Figure 6.9).

An anomalously high- $\delta^{18}$ O granitoid (MM26306) does not fit an array between the depleted mantle and C1/C2 components, and instead suggests mixing with alternative end-members. It may simply be a case that the crust is highly heterogeneous in oxygen, and that the small sample population of this study has fortuitously fallen into two clusters. However, an alternative process is suggested that accounts for the array displayed by the high- $\delta^{18}$ O granite. This process involves mixing between young high- $\delta^{18}$ O sediments (C3) and older high- $\delta^{18}$ O crust (C1). The mixing proportions for this granite require 40-70% of the older crustal component. The introduction of the C3 component to a lower crustal melt generation zone may have occurred via underthrusting during subduction that preceded the continent-continent collision. Such a scenario is advocated for the Grenvillian Frontenac terrane in Laurentia (Peck et al. 2004). However, in this example a whole terrane exhibited a much higher oxygen value than the adjacent terranes. In the example discussed here, it is a single granite that has a much higher  $\delta^{18}$ O value than surrounding granites. Thus, this model is rather speculative and requires further data to be tested. It is worth noting that the geochemistry of the high- $\delta^{18}$ O granitoid is indistinguishable from granitoids with lower  $\delta^{18}$ O; thus highlighting how in-situ zircon data can recognise magma source changes that whole-rock data cannot distinguish. Mixing calculations in this study are compatible with the Nd-Sr mixing calculations of Andersen et al. (2001), which suggest 30-55% of a crustal component for the HBG suite and 20-35% for the Feda suite; with the crustal component having a  $T_{DM}(Nd)$  of 1.9 Ga. The mixing calculations of previous studies, and those described above, do not include the presence of ~1.5 Ga crust. Since crust of such age dominates the exposed upper- crust in the region, it likely did have a contribution to Sveconorwegian magmatism. Evidence for this is provided by  $\sim 1.5$  Ga inherited zircons in various granites (Table 10.4; Bingen et al. 2005b; Andersen et al. 2009b). Andersen et al. (2009b) advocate three crustal sources for Sveconorwegian granitoids: 1.7 Ga granitoids similar to young members of the TIB, 1.5 Ga felsic igneous rocks, and 1.2 Ga juvenile granitoids; these crustal sources are indicated to have mixed with juvenile mantle-derived material. This hypothesis is compatible with the Hf-O data presented in this study, however, it is expected that the C1 and DM end-members probably contributed much less material than that indicated by two-component mixing, and that the Telemarkian crust had a much larger contribution. In summary, the Hf-O data suggest supracrustal material (weathered sediments) contributed to the magma source of the Sveconorwegian granitoids. The magma source is equivalent to both 1.5 Ga crust, and to a mixture of older crust (~1.7 Ga) and mantle. In-situ Hf data from previous studies have recorded zircon inheritance that suggests input of older (~>1.7 Ga) and younger (~1.2 Ga) components.

#### 6.7.6 Reconciling the Hf-O and geochemical constraints

The following two notions can be reconciled into one model that accounts for all of the data: 1) The whole-rock geochemistry of the granitoids suggests derivation from mafic lower crust, which likely occurred via partial melting and fractionation of mafic lower crustal melts to form mafic/intermediate parent magmas, and fractionation of these parent magmas to form the various granitoids (Vander Auwera et al. 2003, 2008; Bogaerts et al. 2003; 2006). 2) The Hf and O (along with previous Hf, Nd and Sr) isotope data indicate contribution from crust that is ~1.5 Ga, ~1.7-1.9 Ga, and ~1.1-1.2 Ga in age, combined with younger mantle-derived material (Andersen et al. 2001, 2002a, 2007b, 2009b; Bingen et al. 1993; Bogaerts et al. 2003).

The origin of a high- $\delta^{18}$ O signature in the older crustal components is largely related to burial of late Palaeoproterozoic supracrustal material and its remobilisation during ~1.5 Ga Telemarkian magmatism (see Chapter 5); continental crust formation via arc magmatism at ~1.5 Ga would have left a residual mafic lower crust that retained a high- $\delta^{18}$ O signature, and a geochemical signature typical of subduction-related magmatism. Underplating may have occurred at 1.2 Ga (Andersen et al. 2007b), adding mafic crust with mantle-like isotopic signatures to the lower crust. During the Sveconorwegian period, the mafic lower crust, in particular its base, will have acted as a zone of mixing, assimilation, storage and homogenisation (i.e. MASH zone; Hildreth & Moorbath 1988). Melting in this MASH zone region produced parent magmas to the Sveconorwegian magmatic suites. The rather homogeneous isotope and geochemical signatures thus result from derivation from a homogenised mafic lower crustal source. Differences in granite geochemistry result from varying water content (along with smaller effects of oxygen fugacity and pressure). Formation of the Rogaland AMC suite from the same mafic lower crustal source region is compatible with this model; Re-Os data suggest derivation from 1.4-1.55 Ga mafic lower crust (Schiellerup et al. 2000), and Nd-Sr suggest >1.5 Ga crustal components and <1.2 Ga mantle components (Menuge 1988; Bolle et al. 2003a).

#### 6.7.7 Geodynamic setting

The protracted period of magmatism (~1070-920 Ma) requires a significant heat source; this in turn can be related to the tectonic setting and geodynamic regime of the crust in question. The Feda Suite has an ambiguous origin, either relating to crustal thickening during the Sveconorwegian orogeny, or to the late stage of an active continental margin that existed prior to continent-continent collision (e.g. Bingen et al. 2008c). Early Sveconorwegian granites dated at 1039-1069 Ma are emplaced in a region that suffered little effects of the Sveconorwegian orogeny (Slagstad et al. 2008; Chapter 3), and metamorphism related to crustal thickening is not recorded until 1035 Ma (Bingen et al. 2008b), thus, a subduction-setting is favoured for the early-Sveconorwegian granitoids. This setting will also provide a volatile flux for producing the hydrous magmas (magnesian members of the Feda suite). During the peak continent-continent collision phase, the crust is inferred to be overthickened (Bingen et al. 2008b); this may have provided further heat for lower crustal melting. Between 980 and 940 Ma the geodynamic regime in the region changed from compressional to extensional (Bingen et al. 2008b), voluminous granitoid emplacement in this period suggests a continued heat flux to the lower crust. The late-Sveconorwegian granites <970 Ma, have been explained by rise of asthenosphere after delamination of underthrust lithosphere (Vander Auwera et al. 2003; Duchesne et al. 1999); this model is partly explained by the linear alignment of the HBG Suite in relation to the Mandal-Ustaoset Shear Zone. Thus, the origin of heat flux to the lower crust has varied over the Sveconorwegian period; however, there are no distinct pauses or changes in magmatism that can identify a change in geodynamic regime.

#### 6.7.8 Continental growth during Sveconorwegian magmatism

Determining the extent of juvenile mantle addition to the magmatic suites has its inherent problems; the low Lu/Hf of both zircons and crustal rocks means that even in a hundred million years, the measured <sup>176</sup>Hf/<sup>177</sup>Hf ratio will not change significantly enough to be discernable. For example, in this study the mantle component in bulk-mixing modelling is calculated using depleted mantle at 950 Ma, however, the youngest mantle contribution could be mafic underplate that is as old as 1.2 Ga (Andersen et al. 2007b). Thus, the data point to contribution from mantle that is 1.2 Ga or younger, but also indicate a significant proportion of recycled crust that is ~1.5 Ga and older. Overall, the Sveconorwegian period has seen a significant degree of remobilisation of older crust,

and a limited volume of crustal growth (mantle addition). This crustal remobilisation (or intracrustal recycling), where felsic plutons form in the upper crust and mafic residues are produced in the lower crust, is an important process that aids the stratification and differentiation of the continental crust.

# 6.8 Conclusions

Voluminous granitic magmatism occurred in southwest Norway from ~1070 to 920 Ma. All granitoids display features associated with subduction-related magmatism, i.e. alkali-calcic to calcalkaline, metaluminous to weakly peraluminous, and depletion in Nb, Ti, and P. The early- to syn-Sveconorwegian granitoids feature both magnesian (I-type) and ferroan (A-type) magma series. The late-Sveconorwegian granitoids are more iron-enriched and have a greater A-type signature. The Fennefoss suite (not sampled; Bingen & van Breemen 1998) has geochemistry transitional but more towards the ferroan suites. The change between ferroan and magnesian magma series can be explained by changes in crystallising conditions (namely the water content) as opposed to changes in magma source.

Magmatism prevailed during differing geodynamic regimes, from supra-subduction, to collisional, and then to extensional. Throughout these different regimes the heat source will have varied; however, both the magma source and the process of granite production likely stayed the same. The Hf-O data suggest the magma source involved a large contribution from crust ~1.5 Ga and older, as well as a contribution from mantle-derived material that is 1.2 Ga or younger. This magma source was mafic lower crust that had homogeneous isotopic and geochemical characteristics imparted from previous magmatic episodes, and that was partially melted and fractionated to form parent magmas to the individual granitoid suites.

This study highlights: 1) how weathered continental crust may contribute to the source of I and Atype granitoids, 2) how such granitoids can form in a variety of tectonic settings as long as there is significant heat flux, and 3) how the conditions in the melt generation zone impart the strongest control on the geochemistry and petrography of granitoid suites.

# The 1.24 Ga Grossæ-Totak suite, a new age confirms an old correlation in the Telemark supracrustals, southern Norway

**Aim** – This chapter presents the first U-Pb age from the Grossæ-Totak belt in the Telemark Sector. Correlations between this and other supracrustal belts within SW Fennoscandia are discussed, as is the tectonic setting of 'interorogenic' units within the region.

# 7.1 Introduction

From ~1800 to 1500 Ma, Fennoscandia is considered to have grown along its southwestern margin via oceanward migration of a long-lived subduction zone (Åhäll & Connelly 2008), i.e. a retreating accretionary orogen (Cawood et al. 2009). The Telemarkia block is suggested to represent a continuation of this south-westerly growth, thereby extending continental growth via arc magmatism to at least ~1460 Ma (see Chapters 4, 6 and 9; Slagstad et al. 2008). Following the 1.8-1.46 Ga growth of SW Fennoscandia, the crustal domains were subject to repeated episodes of magmatism. These have previously been referred to as interorogenic events (Åhäll & Connelly 1998; Bingen et al. 2003); however, it is now increasingly recognised that these magmatic events likely occurred in response to convergent-margin processes on the SW margin of Fennoscandia (Brewer et al. 2004; Söderlund et al. 2005; Söderlund & Ask 2006).

Within the Telemarkia terrane, the Suldal and Hardangervidda Sectors are home to the Sæsvatn-Valldall rift basin that formed at ~1.26 to 1.21 Ga (Bingen et al. 2002; Brewer et al. 2004). In the Telemark Sector, rift basins formed earlier at ~1.5 Ga (Vestfjordallen Supergroup, Laajoki et al. 2002; Dahlgren 1990), and later at ~1.16 Ga (Sveconorwegian Supergroup, Laajoki et al. 2002, Bingen et al. 2003). In the Setesdal region of southern Telemark, supracrustal deposition and calcalkaline plutonism occurred between 1320 and 1200 Ma (Pedersen et al. 2009); the exact tectonic setting during this period is undefined, but the geochemistry points to a supra-subduction zone setting. The extensional basins that formed in the Telemarkia terrane are typically not correlated across the Mandal-Ustoaset Shear Zone which separates the Suldal and Rogaland Sectors from the Telemark Sector (Figure 7.1). In the original mapping of this region (Sigmond 1975, 1978), the Grossæ-Totak supracrustal belt in Telemark was speculatively correlated with the Sæsvatn-Valldall supracrustal belt is not included in published map figures and is not defined in the tectonostratigraphy e.g.Corfu & Laajoki 2008), but is assumed to correlate with the younger 1.17-1.14 Ga Sveconorwegian Supergroup (Bingen, pers. comm. 2010).

# 7.2 Geological Setting

The Telemarkia block comprises four sectors; the Telemark Sector in the east, and the Rogaland, Suldal and Hardangervidda Sectors in the west. In Hardangervidda the oldest outcropping rocks may be as old as 1.65 Ga (Ragnhildsvet et al. 1994). However, gneisses with >1.5 Ga zircon ages have since been interpreted as paragneiss units (Bingen et al. 2005b). In all of the sectors the basement comprises volcanic-plutonic gneisses and granitoids that are 1.55-1.46 in age and likely formed in a continental arc setting (Bingen et al. 2005b; Chapter 4). The Sæsvatn-Valldall supracrustal belt formed within the Suldal Sector at 1.26-1.21 Ga (Bingen et al., 2002; Brewer et al., 2004). At 1.22-1.16 Ga, orthopyroxene-bearing granitoids intruded the Rogaland Sector (Slagstad et al. 2008; Zhou et al. 1995). Abundant metasediments within the Rogaland Sector, including those with passive-margin facies, are suggested to have formed within an extensional basin that formed as Rogaland rifted away from Suldal (Slagstad et al. 2008). The Sirdal Zone (Slagstad et al. 2008) that divides the Rogaland and Suldal Sectors comprises ~1.05 Ga porphyritic granitoids that formed as a result of convergent-margin magmatism possibly related to the subduction of Rogaland under the Suldal Sector (Slagstad et al. 2008), although they may also reflect crustal melting after thickening during the early stage of the Sveconorwegian orogeny (Bingen et al. 2008c). Late-Sveconorwegian granites (0.98-0.93 Ga; Andersen et al. 2002a, 2007a) and a 0.93 Ga Anorthosite-Mangerite-Charnockite complex (Schärer et al. 1996) intruded the Rogaland and Suldal Sectors after the main collisional phase of the Sveconorwegian orogeny.

The Telemark Sector features a >10km thick succession of supracrustals comprising the 1.5->1.35 Ga Vestfjorddalen, and 1.16-1.10 Ga Sveconorwegian Supergroups (Laajoki et al. 2002). The Vestfjordallen Supergroup comprises the bimodal 1.51 Ga Rjukan Group and the overlying sedimentary Vindeggan Group..Bimodal magmatism is related to continental extension that occurred inboard of a subduction zone in a setting similar to the Granite-Rhyolite provinces in the mid-continental US (Slagstad et al. 2009). The Vemork Formation that is part of the Rjukan Group is dominated by metabasalt units; an intercalated metavolcanite is dated at  $1495 \pm 2$  Ma (Laajoki & Corfu 2007). The 5km thick Vindeggan grous comprised mostly of quartz-rich strata; a crosscutting diabase intrusion dated at 1347 ± 4 Ma (Corfu & Laajoki 2008) places a minimum age constraint on sedimentary deposition within the group. The Sveconorwegian Supergroup comprises bimodal volcanic and sedimentary sequences deposited between 1.17 and 1.12 Ga (Laajoki et al. 2002; Bingen et al. 2003), that formed in extensional basins inboard of a continental arc (Brewer et al. 2004), or in a Basin and Range setting (Bingen et al. 2003). Intrusions in the Telemark Sector include 1.22-1.2 Ga juvenile granitoids (Andersen et al. 2007b), 1.19-1.13 Ga A-type plutons (Bingen et al. 2003), and a 1.03 Ga suite transitional between calc-alkaline and A-type (Bingen & van Breemen 1998). The Setesdal valley in the southwest of the Telemark Sector is host to the

Figure 7.1. Map of SW Fennoscandia highlighting post-1.5 Ga and pre-Sveconorwegian units. RVA = Rogaland Vest-Agder, MUSZ = Mandal-Ustaoset Shear Zone.

Figure 7.2. Map of the southern part of the Telemark supracrustals, showing the location of the dated Fjellhovdane metarhyolite (F11). Modified after Bingen et al. (2003) and Corfu & Laajoki (2008).

# 7.3 Sample description and results

The sample that has been dated is a metarhyolite from the Fjellhovdane unit towards the base of the Totak sequence (Figure 7.3), and formed part of the study of the Telemark supracrustals undertaken by Brewer (1985). The sample comprises fine-grained quartz and feldspar, with epidote, Fe-Ti oxides and rare muscovite; coarser quartz grains have developed into stringers. Zircon occurs as an accessory phase.

Figure 7.3. Stratigraphy of supracrustal belts within Telemarkia, based on Sigmond (1978), Bingen et al. (2002), Brewer et al. (2004) and Corfu & Laajoki (2008).

U-Pb geochronology used the LA-ICP-MS method outlined in Chapter 3; the zircons were not chemically abraded. 18 analyses provide a weighted mean  $^{207}$ Pb/ $^{206}$ Pb age of 1238 ± 10 Ma (MSWD = 3.6), using an external error of 34 Ma. This age is interpreted to reflect the crystallisation of the rhyolite.

Figure 7.4. U-Pb concordia showing results of LA-ICP-MS dating of the Fjellhovdane rhyolite.

# 7.4 Discussion

In regional maps, the Grossæ-Totak supracrustal belt is grouped under the Sveconorwegian Supergroup, and is thus assumed to have a 1.17-1.14 Ga depositional age. The 1236 Ma age of the Fjellhovdane rhyolite shows that the Grossæ-Totak belt is older than the Sveconorwegian Supergroup, and is in fact much closer in age to the Sæsavtn-Valldal Belt in the Suldal Sector (1.26-1.21 Ga; Bingen et al. 2002; Brewer et al. 2004). As well as a similar age, the Grossæ-Totak and Sæsvatn-Valldal belts have similar characteristics that suggest they formed by similar tectonic and magmatic processes, namely, early rhyolitic volcanism followed by voluminous basaltic volcanism, with intercalated quartz-rich sediments (Brewer et al. 2004). The geochemistry and whole-rock Nd and Hf isotope systematics of the Sæsvatn-Valldal Belt are interpreted to represent rhyolite formation by crustal anatexis, early basaltic volcanism involving significant crustal contamination, and later basaltic volcanism tapping a mantle source and undergoing less crustal contamination (Brewer et al. 2004). The initial crustal anatexis is produced by basalt intrusion into the crust as a consequence of lithospheric thinning (Brewer et al. 2004). The geochemistry of the Grossæ-Totak rhyolites is similar to the Trossovdal rhyolites of the Sæsvatn-Valldall belt (Figure 7.5), suggesting that similar crustal rocks underwent melting to form the rhyolites. Both suites feature highly enriched LILE, enriched HFSE, elevated LILE/HFSE ratios, and relative depletion in Nb, Sr, P and Ti. These features are suggestive of a continental arc setting (Wilson 1989; Pearce 1982). In the Suldal Sector, Telemarkian rocks likely formed in a continental arc setting (Chapter 4), and thus provide a potential candidate for crustal protoliths that underwent melting to form the rhyolites in the Sæsvatn-Valldall belt. In the Telemark sector, similar age lithologies are not recorded at the surface, which is largely due to the more widespread younger sedimentary cover in this region. Assuming the Fjellhovdane rhyolite formed by the same tectonothermal process as for the formation of the Trossovdal rhyolite, the geochemistry suggests that continental arc rocks are located at depth within the Telemark Sector, lending support to the hypothesis that the Telemark block grew by continental arc magmatism in the Telemarkian period (Bingen et al. 2005b).

Figure 7.5. Primitive Mantle normalised (Sun & McDonough, 1989) plot for felsic units within the Sæsvatn-Valldall belt (Trossovdal), Grossæ-Totak belt (Fjellhovdane) and metaplutonic/volcanic basement within the Suldal Sector (Sauda). Trossovdal data from Brewer et al. (2004); Suldal data from Chapter 4.

Gneisses of the Vravatn Complex in Telemark are slightly younger than the Grossæ-Totak belt, with ages of ~1220-1200 Ma, and have Hf isotope signatures that suggest formation with a significant depleted mantle input (Andersen et al. 2007b). This juvenile magmatism is interpreted to reflect an episode of mafic underplating in the region (Andersen et al. 2007b). In the Setesdal region, south of the Grossæ-Totak belt, supracrustals were deposited between 1320 and 1200 Ma (Pedersen et al. 2009). Hf isotopes from this region suggest that a change in magmatism from a dominantly older crustal input to a juvenile input occurred between 1220 and 1215 Ma (Pedersen et al. 2009). This provides further supporting evidence for mafic underplating of the crust. The deposition of volcanic and sedimentary rocks with associated juvenile mafic intrusions, spanning the period from 1320 to 1200 Ma, is probably linked to the same long-lived tectonic process. This involved mafic underplating and intrusion, crustal anatexis, and continental sedimentation in rift basins. As suggested by Brewer et al. (2004), the lithospheric extension that allowed for these processes was likely linked to extension of the overriding plate in a subduction setting, i.e. the extensional basins are back-arc expressions of a long-lived convergent margin. Continental arc rocks of equivalent age are not recorded in the region, although the Tromøy Block located off the

southeast coast of Telemarkia does have a postulated island-arc origin (Knudsen & Andersen 1999), attesting to convergent margin processes in the region. If a continental arc located to the west of Telemarkia did exist at 1300-1200 Ma, then this crust must have been recycled by subduction erosion, or translated to a different continental region during the Sveconorwegian orogeny.

In the eastern parts of the Southwest Sveconorwegian Domain (SSD) the magmatic record for the 1300-1200 Ma time period is dominated by mafic magmatism in localised extensional settings. This includes the 1300 Ma Våstergotland dolerite suite in the Idefjorden terrane, the 1.27-1.26 Ga Central Scandinavian Dolerite Group across central Scandinavia, and the 1.22-1.2 Ga Protogine Zone dolerites in the Eastern Segment/Idefjorden terrane boundary zone (Söderlund et al. 2005). The latter features granite and syenite intrusions as well as mafic magmatism (Johansson 1990).

The 1300-1200 Ma events in Telemarkia are distinct from those in the eastern part of the SSD, i.e. in the west there was basin formation with deposition of sediments and associated bimodal volcanism, and in the east there was localised mafic magmatism with minor felsic magmatism. This contrast lead Corfu & Laajoki (2008) to suggest a more outboard and exotic origin for the Telemarkia terrane, as similar characteristics are recorded in the Composite Arc Belt of the Grenville province in Laurentia (Carr et al. 2000). However, the Dal Group in the Eastern Segment is an extensional basin that is interpreted to be a more distal equivalent of ~1.16 Ga supracrustals in the Sveconorwegian Supergroup (Bandak Group; Brewer et al. 2002). The Dal Group comprises quartzite, slate, mafic volcanics, and arkose that are interpreted as forming in a rift basin (Alm et al. 1997; Lundberg 1973), with deposition bracketed between 1.05 and 1.33 Ga (Romer & Smeds 1996; Piontek et al. 1998). Thus, although the timing of Dal Group deposition is not well constrained, it provides a link between the western and eastern parts of the SSD.

At ~1300-1200 Ma, the contrast between extensional basin formation in Telemarkia and formation of discrete mafic intrusions in Idefjorden and further east, may be a consequence of the difference in thermal properties of the crust. The younger Telemarkia block may have been a warmer, more mobile and thus weaker domain, whereas the older Idefjorden and Eastern Segment were probably colder, thicker and stronger crustal domains. This difference led to broad and widespread extension in Telemarkia and discrete more localized extension in the east.

# 7.5 Conclusions

A U-Pb age of  $1238 \pm 10$  Ma for the Fjellhovdane rhyolite indicates that the Grossæ-Totak supracrustal belt is older than the Sveconorwegian Supergroup (1.17-1.14 Ga), and overlaps in age with the Sæsavtn-Valldal supracrustal belt (1.26-1.21 Ga). This confirms a correlation made by Sigmond (1978) in the original mapping of the region. This age widens the temporal and spatial

extent of 1300-1200 Ma magmatism, and suggests that the tectonostratigraphy of the supracrustals in the Telemark Sector needs revision. The Grossæ-Totak belt is interpreted to be part of a widespread extensional phase affecting southern Norway, which occurred in response to a convergent margin that likely existed to the west of the current Norwegian coastline.

# In-situ U-Pb and Hf isotopes constrain the age & provenance of the Hardangervidda-Ryfylke Nappe Complex, SW Norwegian Caledonides

Aim - This chapter presents the first U-Pb and Lu-Hf data from Caledonian nappe units exposed in the Suldal Sector; the data are used to constrain the age and provenance of nappe units from a variety of structural levels. Correlations with nappe complexes elsewhere are discussed, as are insights into the Mesoproterozoic history of Fennoscandia.

# 8.1 Introduction

The Scandian phase of the Caledonian orogeny resulted in the continental margin of Fennoscandia being subducted underneath Laurentia, imbricated and thrust eastwards onto the foreland, with nappe displacements of up to several hundreds of kilometres (Roberts & Gee 1985). The Caledonian nappes have been traditionally divided into the Lower, Middle and Upper Allochthons. The Lower Allochthon comprises Precambrian basement and overlying cover sediments that can be correlated with autochthonous units; the Middle Allochthon comprises allochthonous Fennoscandian Precambrian basement and cover sediments from the continental margin and ocean-continent transition zone; the Upper Allochthon comprises lower Iapetus-derived oceanic units; and above this the Uppermost Allochthon comprises exotic units that are inferred to have a Laurentian ancestry (e.g. Gee 1975; Roberts & Gee 1985; Stephens & Gee 1985; Roberts 2003).

The Precambrian crystalline units found within the Caledonian nappes likely are parts of the Fennoscandian basement and record the Mesoproterozoic growth of Fennoscandia, including the continent's evolution during the amalgamation and break-up of the supercontinent Rodinia. Thus, the information recorded in the Caledonian nappe units is relevant to aid our understanding of palaeotectonics in the Precambrian of the Baltic Shield. Studies of the Scandinavian Caledonides have traditionally focussed on key areas (e.g. the Western Gneiss Region), leaving other regions less understood. The Hardangervidda-Ryfylke Nappe Complex (HRNC) in SW Norway is one such area, having received little attention since being mapped in the seventies (Naterstad et al. 1973; Andresen 1974; Sigmond 1975). The lack of U-Pb geochronology conducted on this nappe complex is especially hindering correlation with units elsewhere in Scandinavia.

# 8.2 Geological Setting

The allochthonous rocks south of the Hardangerfjord were grouped together as the Hardangervidda-Ryfylke Nappe Complex by Naterstad et al. (1973). In the Haukelisater-Røldal area, the HRNC can be subdivided into three allochthonous units (Andresen & Færseth 1982), these are (from the base

Figure 8.1. Geological map of the southern Norwegian Caledonides, and sample localities (indicated by arrows). After Gee et al. 2008; Sigmond 1975.

upwards) the Holmasjø allochthon, Nupsfonn allochthon, and the Dyrskard-Kvitenut-Revsegg allochthon. These units are separated by ductile shear zones that formed in amphibolite-facies (Andresen 1974). Southwest of Haukelisater-Røldal in the Sauda-Suldal area, two nappe units have been recognised, these are the Buadal and Storhei units (Sigmond 1978). The same units cannot be traced all the way from Hardangervidda southwest to the coast, this is due to both displacement along shearzones within the nappe complex, and the limited of extent of some units; however, similarities in the general structure of the complex do exist in all areas. Thus, the term Hardangervidda-Ryfylke Nappe Complex and its reference to the entire complex of nappes outcropping south of the Hardangerfjord are kept here. The following is a summary of published data on the nappe units of the HRNC that are sampled in this study; for further review the reader is referred to Sigmond (1978) and Andresen & Færseth (1982).

Figure 8.2. Tectonostratigraphy of the Hardangervidda-Ryfylke Nappe Complex, including new and published ages. Modified from Sigmond (1978) and Andresen & Færseth (1982).

# 8.2.1 Holmasjø unit (Lower Allochthon)

The Holmasjø unit comprises non-calcareous schists and phyllites commonly interspersed with thin quartzite layers and pods. The unit is metamorphosed in greenschist facies, with biotite and garnet formation recorded in some areas, although retrogression to chlorite is widespread (Naterstad et al. 1973). Polyphase deformation is evident in the unit. Low-angle thrust faults dip northwest and trend northeast-southwest; the transport direction along these is thought to be to the southeast and east, but with the dominant deformation phase being that of extension or back-thrusting to the northwest (Andresen & Færseth 1982). Locally, faults cut down into the basement so that basement slices can be found along the base of the unit (Andresen & Færseth 1982). Phyllites were dated in the Hardangervidda region by whole-rock Rb-Sr, giving an age of  $409 \pm 15$  Ma (Andresen et al. 1974).

The basal allochthon in the Suldal region, which has been correlated with the Holmasjø unit, contains a metaandesite that has been dated by whole-rock Rb-Sr at  $1145 \pm 98$  Ma (Sigmond & Andresen 1976). Holmasjø Unit phyllites in the study area are thought to represent a deeper water facies of the Cambrian to Lower Ordovician sediments of the Parautochthonous Vidda Group (Andresen 1978); in this case the Precambrian metaandesite may represent a thin thrust slice of crystalline basement caught up with younger cover sediments.

#### 8.2.2 Storhei unit (Middle Allochthon)

The Storhei unit is dominantly composed of layered gneisses, with subordinate augen gneiss, quartzite and amphibolite layers; the layered gneisses may have supracrustal origins (Sigmond 1978). Previous work suggests that the top of the unit comprises charnockitic gneisses, with acid to basic compositions and both foliated and massive varieties (Sigmond 1978). Diabase dykes with garnet and clinopyroxene intrude the charnockitic gneisses (Sigmond 1978). The layered gneisses are amphibolite-grade, with staurolite occurring west of Saudafjord (Sigmond 1978). The charnockitic rocks have reached granulite-facies, with the assemblage clinopyroxene-hypersthene-garnet-plagioclase-quartz recorded in massive gneisses; in the foliated rocks this is present as relics or has been replaced by amphibolite-facies assemblages (Sigmond 1978). No rocks within the Storhei or underlying Buadal nappe have been previously dated. The boundary between the Storhei and underlying units is a mylonitic thrust zone, but is gradational in terms of lithological change (Sigmond 1978).

#### 8.2.3 Dyrskard unit (Middle Allochthon)

The Dyrskard unit is composed of volcanic and sedimentary supracrustal rocks, dominated by metabasalts, metarhyolites and quartzites (Andresen & Gabrielsen 1979). From the base upwards the unit comprises 1) banded supracrustal gneisses, 2) quartzite, feldspathic sandstones and mica schists with minor basic to intermediate metavolcanics, 3) amphibolites with quartzite and marble horizons, and 4) acid metavolcanics (Gabrielsen 1980). Metabasalts have a restricted extent, whereas the metarhyolites are widespread (Gabrielsen 1980). Kyanite in a mica-schist, a plagioclase-amphibole-garnet assemblage in the amphibolites, and the lack of migmatisation, attest to medium-grade metamorphism under relatively high pressure (Sigmond 1978). Chlorite after biotite/amphibole records retrogression in greenschist-facies (Andresen 1974). Polyphase deformation is evident within the unit; the oldest phase occurred prior to thrusting of the overlying nappe units, and the youngest phase represents Caledonian folding (Sigmond 1978). Five samples from varying lithologies gave a whole-rock Rb-Sr isochron of 1289  $\pm$  80 Ma (Andresen et al. 1974). Another age determination was made at c. 1520 Ma (Gabrielsen & Solheim, in Gabrielsen & Solheim 1980), with the authors concluding that the 1289 Ma age was a mixed age and unreliable.

Thrust zone blastomylonites that occur between the Dyrskard and the overlying Kvitenut unit have also been dated by whole-rock Rb-Sr, giving an age of  $1504 \pm 41$  Ma (Gabrielsen et al. 1979).

#### 8.2.4 Kvitenut unit (Middle Allochthon)

The Kvitenut unit comprises quartzofeldspathic gneisses with subordinate calc-silicate rocks and migmatised gneisses. The lowermost part of the unit features mylonitic gneisses, whereas migmatite formation occurs in the upper part of the unit (Naterstad et al. 1973). Minor lithologies within the banded gneisses include marble, mica schist, diopside fels and plagioclase-diopside-epidote rocks (Andresen 1974). Gneissic intrusive bodies ranging from gabbro to granite that cut earlier fabrics are common, but do not cut the boundary into the underlying Dyrskard unit (Naterstad et al. 1973; Andresen & Færseth 1982). The migmatisation and development of schlieren in amphibolitic rocks, and the sillimanite/kyanite assemblages attest to medium- to high-grade metamorphism under medium to high pressure (Sigmond 1978). However, most of the unit has been retrogressed to amphibolite facies (Andresen 1974). The unit features multiple stages of deformation, most of which occurred in amphibolite-facies conditions and are interpreted as pre-Caledonian (Andresen & Færseth 1982). Some of the deformation occurred prior to thrusting of the unit above the underlying Dyrskard unit. An amphibolite gneiss has been dated by whole-rock Rb-Sr at 1643  $\pm$  88 Ma (Andresen et al. 1974), which was interpreted as a metamorphic age.

#### 8.2.5 Revsegg unit (Middle Allochthon)

The Revsegg unit is composed of muscovite-biotite gneisses with quartzo-feldspathic pods, concordant boudins of amphibolite and some cross-cutting intrusive bodies (Naterstad et al. 1973). The dominant rock type is a two-mica gneiss that has a variably developed schistosity. Interbedded with the mica gneiss is a hornblende-biotite gneiss that is commonly boudinaged. Large intrusive bodies are not found, but minor bodies of granodiorite and quartz-diorite apparently postdate the peak metamorphism and earliest structures (Andresen & Færseth 1982). The Revsegg unit is interpreted to have been deposited on the underlying Kvitenut unit (Naterstad et al. 1973), although this remains to be proven. The mineral assemblage biotite-muscovite-garnet-sillimanite/kyanite suggests medium-grade metamorphism under medium pressure (Sigmond 1978). The deformation recorded in the Revsegg unit is similar to that in the Kvitenut complex. Revsegg gneisses have been dated by whole-rock Rb-Sr and give ages of  $440 \pm 250$  Ma (Andresen et al. 1974) and  $1316 \pm 80$  Ma (Gabrielsen & Solheim 1980). The latter age was interpreted as a mixed age but constraining a minimum age for deposition, and the younger age indicates an influence from the Caledonian orogeny.

# 8.3 Rationale for isotope work

The scarcity of Rb-Sr age determinations and the questions over their reliability in mixed age populations, and the lack of any U-Pb dating, means a number of key issues relating to the HRNC

remain unresolved. For example: 1) does the tectonostratigraphy represent sequential emplacement of nappe units from more distal locations upon more proximal units, i.e. does the stratigraphically highest unit represent the most distal unit? 2) related to the former question, do the nappe units young upwards as would be expected from simple imbrication and stacking of the continental margin? 3) what age are the cross-cutting rocks described in some units and do they correlate with

Figure 8.4. Thin section photomicrographs of sampled Middle Allochthon gneisses.

Sveconorwegian, Neoproterozoic or Caledonian events recorded elsewhere? 4) Do any of the nappe units correlate with Mesoproterozoic autochthonous rocks within the region? To answer some of these questions, one sample was collected and analysed from each of five different nappe units.

# 8.4 Sample Description

### 8.4.1 SA8-32 Holmasjø Unit (fine-grained intermediate grey gneiss)

SA8-32 is an aphyric massive fine-grained grey gneiss of intermediate composition. The sampled outcrop comprises decimetre scale bands of aphyric and feldspar-phyric units of similar composition that feature a weakly developed planar fabric. The outcrop was poorly exposed so that tracing with other units was not possible, but the location matches the description of metaandesitic gneisses previously dated at 1145 Ma (Sigmond & Andresen 1976). The sample is composed of fine to medium-grained quartz, feldspar, amphibole, biotite and epidote, with abundant retrogression of biotite and amphibole to chlorite. Separated zircons are prismatic, elongate and feature oscillatory zoning. Some grains feature truncations between cores and outer zones, and many feature thin CL-bright rims.

### 8.4.2 SA8-19 Storhei Unit (coarse-grained granitic gneiss)

SA8-19 is a weakly deformed coarse-grained granitic gneiss. The sample was taken from poorly exposed weathered outcrops on the summit of Vardanuten. Other lithologies in the area include white feldspar-rich veins, and migmatitic gneisses with well-developed leucosome formation. The location correlates with the charnockitic gneisses mapped by Sigmond (1975). The sample comprises quartz, feldspar, actinolite and biotite. The mafic minerals are variably distributed and occur as individual laths, schlieren, or up to 3cm-across aggregates in less-foliated areas. Feldspars are both plagioclase and microcline, and also feature myrmeckite development. Opaque grains are complex and include rutile overgrowths on ilmenite. Exsolution textures are visible in the opaques and in the other mafic minerals. Although no pyroxene or garnet was observed, the exsolution and overgrowth textures suggest a possible relic high-grade metamorphism. Separated zircons are generally elongate and oscillatory zoned, often featuring irregular zones or embayments that may represent alteration and/or metamictisation. Truncations between core and outer zones exist in some grains, and a few also feature CL-bright rims.

## 8.4.3 SA8-23 Dyrskard Unit (fine-grained felsic gneiss)

SA8-23 is a fine-grained quartz-feldspar gneiss with a strong planar fabric. The outcrop features bands (likely originating as bedding) of this felsic gneiss, along with bands of more intermediate composition which are typically feldspar phyric. The outcrop matches the description of acidic banded gneisses that occur in the upper parts of the Dyrskard Unit (Gabrielsen 1980). The sample is composed of fine-grained quartz, feldspar, biotite, muscovite, epidote and opaque grains. A fabric is

seen as alignment of mica laths, and development of coarser bands of quartz and feldspar. The geochemistry of the sample (figure 8.7) indicates a rhyolitic protolith was likely for this sample. Separated zircons are prismatic, generally elongate, and feature regular oscillatory-zoning. There is a lack of truncations between growth zones, and the grains do not exhibit any metamorphic or alteration rims.

### 8.4.4 SA8-26 Kvitenut Unit (mylonitic banded gneiss)

SA8-26 is a mylonitic gneiss comprising mm- to cm-scale alternating pink, grey and black bands. The sample is taken from the base of a cliff which is interpreted to be the base of the unit; the outcrop comprises mylonitic banded gneisses of varying composition. Felsic bands within the sample comprise quartz, feldspar, and minor biotite, epidote and titanite grains. The more mafic bands comprise a much greater content of biotite, but also feature abundant coarse grains of titanite, epidote minerals and a pale amphibolite. These grains are fairly spherical and rounded, and likely originate as phenocrysts that have been rounded during mylonitisation. The protolith of the sample is not obvious, the description of the unit refers to granodioritic and granitic gneisses (Naterstad et al. 1973), which is generally appropriate for the sampled outcrop; however, it is not clear whether the alternating bands of different composition represent sheared igneous lithologies, or banding due to a sedimentary origin. Separated zircons are of various morphologies and textures, commonly oscillatory zoned, but also sector zoned and some with no obvious zonation; the variety of zircons suggests a sedimentary protolith may be appropriate. CL-bright rims occur on some grains not treated by chemical abrasion (see 8.6); after treatment the chemically abraded grains are often skeletal.

### 8.4.5 SA8-27 Revsegg Unit (garnet two-mica gneiss)

SA8-27 is a mica-rich gneiss quartz-feldspar gneiss, with quartz and feldspar occurring as both finegrained matrix minerals, and also as cm-scale pods. Boudinaged amphibolite pods exist in the sampled area and are concordant to the structural fabric. The sample represents the two-mica gneiss that occurs in the basal part of the unit (Naterstad et al. 1973). Biotite and muscovite are the dominant minerals, and form an anatomising extensional shear fabric. Garnet is abundant, and forms small euhedral grains that are both cross-cutting and aligned to biotite cleavage. Chlorite that has replaced biotite during retrogression is weakly developed. Kyanite was not seen in the thin section but was abundant in the mineral separate, and thus likely forms distinct horizons within the gneiss. Separated zircons exhibit a wide variety of morphologies and textures, which is compatible with a sedimentary origin for the protolith; the abundance of mica suggests a semi-pelitic composition. The chemically abraded grains are typically skeletal, whereas the untreated grains are rounded and commonly feature oscillatory zoning.

# 8.5 Analytical Methods

Analytical methods follow those described in Chapter 3 (U-Pb), Chapter 4 (whole-rock geochemistry) and Chapter 5 (Lu-Hf).

# 8.6 Results – U-Pb

### 8.6.1 SA8-32 Holmasjø Unit (fine-grained intermediate grey gneiss)

Ten non-abraded zircon grains were analysed and all gave nearly concordant ages. Nine out of ten analyses provide a weighted mean  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  age of 1497 ± 6 Ma, with a MSWD of 2.3. The rejected analysis has a slightly younger  ${}^{207}\text{Pb}/{}^{206}\text{Pb}$  age of 1464 ± 10 Ma, and may reflect modest lead-loss due to Sveconorwegian or Caledonian events. The 1497 Ma age is interpreted to represent the crystallisation age of the igneous protolith.

### 8.6.2 SA8-19 Storhei Unit (coarse-grained granitic gneiss)

Nineteen chemically abraded zircons grains were analysed; these were all nearly concordant but gave a spread of ages. Nine overlapping grains form a defined group at  $1480 \pm 20$  to  $1512 \pm 12$  Ma. Three overlapping grains form a slightly younger group at  $1421 \pm 22$  to  $1456 \pm 19$  Ma. Five concordant grains are dated at  $1198 \pm 18$ ,  $1251 \pm 32$ ,  $1302 \pm 18$ ,  $1323 \pm 25$ ,  $1365 \pm 26$  Ma. The two youngest grains are dated at  $1021 \pm 23$  and  $1024 \pm 27$  Ma. Some of the ~1100-1400 Ma grains appear to have analyses that overlap different growth zones; however this is not applicable to all of this population. The age population is interpretable in a number of ways. The sample may represent a sedimentary protolith with a detrital zircon population. Or, the sample may represent a ~1500 Ma protolith with Sveconorwegian overprinting, with ages representing mixtures of these ages. Or, the sample may represent a ~1500 Ma protolith with younger ages representing lead-loss, and Sveconorwegian ages representing new growth. The ~1500 Ma population of zircons feature similar oscillatory zoning and morphologies, with dark outer growth bands. Younger grains also feature similar characteristics. The two Sveconorwegian grains feature more diffuse zoning and less prismatic morphology. A sedimentary origin of these zircons is thus unlikely as a greater variety of morphologies is likely to exist in this case. Since some of the analyses cross different growth zones, some mixing between ~1500 Ma and ~1000 Ma may have occurred. The favoured interpretation is that the two Sveconorwegian grains are new zircon growth during this orogenic event. Lead-loss may have produced some of the younger ages, but is unlikely to be the sole cause in the spread of ages. Thus, the age population is interpreted as a ~1500 Ma protolith age, and a zircon-growth event at ~1020-1030 Ma.

### 8.6.3 SA8-23 Dyrskard Unit (fine-grained felsic gneiss)

Eleven chemically abraded zircon grains were analysed; these were all relics of oscillatory-zoned prismatic grains. All eleven analyses provide a weighted mean  ${}^{207}$ Pb/ ${}^{206}$ Pb age of 1062 ± 4 Ma with

Figure 8.5. Selection of zircon grains and results of U-Pb dating, shown as concordia plots and cumulative probability plots for detrital samples (excluding grains with >10% discordance).

a MSWD of 1.01. The analyses are concordant to weakly reversely discordant; one grain is strongly reversely discordant, but has a  $^{207}$ Pb/ $^{206}$ Pb age that is equivalent to the mean of the group at 1060 ± 20 Ma. The reverse discordance is likely related to inter-element fractionation differences between the sample and standard as a consequence of chemical abrasion (see Chapter 3). The 1062 Ma age is interpreted to represent crystallisation of the igneous protolith.

### 8.6.4 SA8-26 Kvitenut Unit (mylonitic banded gneiss)

41 chemically abraded zircon grains were analysed. 4 inferior analyses were rejected due to high common lead or low <sup>207</sup>Pb signals. 6 of the accepted grains have normal discordance greater than 10%. A multi-age population is exhibited, ranging from 979 to 1674 Ma. On the cumulative probability plot three major peaks are displayed at 1.01 to 1.06 Ga, 1.46 to 1.5 Ga, and at 1.6 to 1.67 Ga. These correspond to early- Sveconorwegian, Telemarkian and early-Gothian magmatic episodes respectively. There are two other concordant grains dated at 1278 ± 12, and 1362 ± 13 Ma. The youngest grain has a <sup>207</sup>Pb/<sup>206</sup>Pb age at 979 ± 29 Ma. The analyses were nearly all conducted on inner cores of grains. Each peak in the cumulative probability plot is represented by zircons with varying morphologies and zoning patterns, suggesting a detrital origin for the zircons, and thus a sedimentary origin for the protolith. The grains are sub-rounded which is compatible with this interpretation, although the chemical abrasion has masked this to an extent. The youngest grain suggests deposition of the protolith after 979 ± 29 Ma, multiple analyses of this grain. A significant population (n=6) of varying morphologies ranging from 1013 to 1062 Ma indicates the maximum age of deposition is younger than this population.

## 8.6.5 SA8-27 Revsegg Unit (garnet two-mica gneiss)

30 chemically-abraded zircon grains and 31 untreated grains were analysed. 2 analyses were rejected due to high common lead or a low <sup>207</sup>Pb signal. 5 of the accepted grains had discordance greater then 10%. A multi-age population is exhibited, ranging from 800 to 1795 Ma. On the cumulative probability plot a major peak is displayed at 0.9 to 1.06 Ga (27 grains). Smaller peaks are at 1.73 to 1.8 Ga (4 grains), at 1.5 Ga (4 grains) and at 1.15 Ga (2 grains). Two other grains are concordant at 0.8 and 1.61 Ga. The three youngest grains have ages of 468 ± 11, 500 ± 14, and 488 ± 14, and occur on CL-dark outer zones and a bright metamict core respectively. The range in morphologies and zoning patterns is compatible with a detrital origin. The ~940 to 960 Ma grains exhibit a range in morphologies, mostly with oscillatory zoning; the 800 Ma analysis is from a core of a grain with zoning typical of igneous zircons. The 470-500 Ma analyses are conducted on outer growth-zones and a metamict core, and are interpreted as zircon growth and metamictisation during early-Caledonian events. In this case, deposition is constrained to be younger than the ~940-960 Ma population, and possibly as young as <800 Ma if this grain represents a true detrital age.

## 8.7 Results – Hf

Each of the three samples interpreted as having igneous origins (SA8-32, SA8-19, SA8-23) has a range in  $\epsilon$ Hf<sub>(T)</sub> of three to four epsilon units, which is within the range of analytical error (typically  $\pm 2\epsilon$ ). Weighted average  $\epsilon$ Hf<sub>(T)</sub> values are 6.0  $\pm$  1.0 for SA8-32 (MSWD = 2.2), 2.5  $\pm$  0.9 for SA8-23 (MSWD = 1.9) and 2.1  $\pm$  1.0 for the ~1500 Ma population of SA8-19 (MSWD = 1.5). These values overlap the field for autochthonous basement of Sveconorwegian and Telemarkian age (Figure 8.6).

Figure 8.6.  $\epsilon$ Hf<sub>(T)</sub> vs. Time (Ma) for HRNC gneisses compared with data for autochthonous basement rocks in SW Fennoscandia (grey fields). Fields are plotted from data in Chapters 5 and 6, and Andersen et al. 2002b, 2004a, 2007b, 2009a; Andersen & Griffin 2004; Pedersen et al. 2009. SA8-23 and SA8-32 are shown as weighted mean averages with the black error bars representing the total range of values including 2sigma error. The 1500 Ma population of SA8-19 is also shown as a weighted mean value. The rest of the SA8-19 data and SA8-27 and SA8-26 are shown as individual analyses with grey error bars representing 2sigma. The depleted mantle (DM) value of Griffin et al. (2000) is used, along with the CHUR values of Bouvier et al. (2008).

The evolution of Lu-Hf in a closed-system zircon will be different to that in a piece of crust due to the difference in the abundance of these elements. Evolution lines are drawn in figure 8.6 for typical continental crust (Lu/Hf = 0.015) and for the average zircon concentration (Lu/Hf = 0.0009), starting at the 1500 Ma population of SA8-19. The younger zircons of this sample have errors in  $\epsilon$ Hf<sub>(T)</sub> which overlap both of these evolution lines, thus, the Hf data cannot distinguish between a lead-loss or mixed age origin for these younger grains.

The detrital samples (SA8-26 and SA8-27) have  $\epsilon Hf_{(T)}$  that broadly correlate with the autochthonous basement rocks (Figure 8.6). There is an abundance of 1650-1700 Ma age grains that do not correlate in age with the basement, however, this likely results from sampling bias, since

1650-1700 Ma age rocks are common within the Eastern Segment and within the Western Gneiss Region (e.g. Tucker et al. 1990; Åhall & Connelly 2008) but do not have published Hf data.

# 8.8 Discussion

## 8.8.1 Origin of the nappe units

### Holmasjø Allochthon

The ~1500 Ma age for the intermediate gneiss (SA8-32) from the Holmasjø allocthon correlates with the Telemarkian (1520-1480) age for much of the autochthonous basement within the region (Bingen et al. 2005b; see Chapter 3). Thrust faults within the unit have been observed to cut down locally into this autochthonous basement (Andresen & Færseth 1982). The displacement of the unit is in the order of several tens of kilometres (Andresen & Færseth 1982). Thus, it seems likely that the sample is from a slice of basement that is locally derived (<100km displacement), and has been imbricated with younger allocthonous phyllites during Caledonian thrusting.

### Storhei Gneiss

The Buadal and Storhei nappe units that make up the crystalline allochthonous units in the Suldal region have little known about them. In the sampled area (east of Saudafjord) the rocks are assigned to the Storhei Nappe, with charnockites occurring in the upper section (Sigmond 1978). The relationship between the charnockitic rocks and the amphibolite-facies gneisses that comprise the rest of the unit is unknown (Sigmond 1978). During this study, the relationship between supposed charnockitic rocks and other gneiss units was not observed due to poor exposure. Definite charnockite lithologies were also not observed, even when they were previously mapped as charnockite. Thus, the possible relic granulite-facies history of gneisses in the Storhei Unit remains to be explored.

The ~1500 Ma age and  $\epsilon$ Hf<sub>(T)</sub> of the Storhei gneiss is similar to that of the Telemarkian age crust that dominates the autochthonous rocks (Figure 8.6). Based on the assumption that the sampled rock has an igneous origin, the Storhei nappe likely comprises Telemarkian crust that existed northwest of the present coastline prior to Caledonian shortening. It is not known whether the sampled gneiss has been disrupted by younger intrusive units, or if high-grade metamorphism occurred at ~1020 Ma or at a younger age. However, granulite-facies rocks are recorded at Stavsnuten in the Kvitenut unit (Andresen 1974), therefore a possible correlation with this adjacent Middle Allocthon unit may exist in terms of metamorphic history.

### Dyrskard Unit

The quartzite-dominated sediments and bimodal volcanics of the Dyrskard Unit are interpreted to have formed in a continental margin environment (Gabrielsen 1980). The geochemistry of the dated

metarhyolite (Figure 8.7) has a signature indicative of a supra-subduction setting (e.g. enriched LILE & negative Nb, Ti, P anomalies). The geochemistry is strikingly similar to metarhyolites (Trossovdal Fm.) of the ~1260 Ma Saesvatn-Valldall sequence that are interpreted to have formed in a continental-rift or back-arc (Bingen et al. 2002; Brewer et al. 2004), that also comprise bimodal volcanics and intercalated sediments. The 1062 Ma age and geochemistry for the Dyrskard metarhyolite is also correlative with autochthonous early-Sveconorwegian granitoids that occur in the region (Chapter 6). These granitoids are related to an E/NE dipping subduction zone that was active prior to continent-continent collision at ~1035 Ma (Bingen & van Breemen 1998; Slagstad et al. 2008), although granitoids of this suite have also been interpreted to result from crustal thickening during Sveconorwegian orogenesis (Bingen et al. 2008c). The geochemistry and sedimentology of the Dyrskard supracrustals is interpreted here to represent deposition in a shallow marine environment located on a fore- or retro-arc foreland basin. This is compatible with the existence of an early Sveconorwegian arc located on the Fennoscandian margin (Slagstad et al. 2008).

Figure 8.7. Primitive mantle normalised (Sun & McDonough 1989) plot of the Dyrskard metarhyolitic gneiss (SA8-23) compared with the ~1260 Ma Trossovdal metarhyolite (Brewer et al. 2004), and ~1050 Ma Feda suite granitoids (see Chapter 6).

## Kvitenut and Revsegg Units

The Kvitenut and Revsegg metasedimentary gneisses were deposited after the main Sveconorwegian orogenic phase within the region (1035-1000 Ma; Bingen et al. 2008c), with single detritus zircon ages suggesting deposition after 979 Ma for the Kvitenut Unit, and possibly as young as <800 Ma for the Revsegg Unit. There are no exact minimum age constraints on the deposition of the sediments, except that they have been deformed during Caledonian orogenesis, with interpreted new zircon growth at ~500 Ma in the Revsegg Unit.

The Revsegg paragneiss contains a much greater content of Sveconorwegian age zircons than the Kvitenut paragneiss, with fewer early-Mesoproterozoic zircons (see Figure 8.8). This may be

related to uplift and increased weathering of the Sveconorwegian-aged crust during the early Neoproterozoic, as has been interpreted for correlative deposits in NW Scotland (Kirkland et al. 2008b). The oldest grains in both samples are c. 1700 Ma, suggesting that 1500-1700 Ma Telemarkian-Gothian crust may have had enough relief to inhibit flow of detritus from Archaean-Palaeoproterozoic sources, this feature has also been attributed for sedimentary deposits in Scotland and Greenland (Cawood et al. 2004).

The metasedimentary lithologies within the Kvitenut and Revsegg units are poorly described; however, the Kvitenut Unit is dominated by quartz-feldspar-rich gneisses, whereas the Revsegg Unit is dominated by mica-rich gneisses. Thus, it seems reasonable to interpret the Revsegg Unit has having a more distal marine origin than the Kvitenut Unit, with mica gneisses in the former representing more pelitic protoliths.

Late Mesoproterozoic to Neoproterozoic sedimentary sequences are found throughout the North Atlantic Region, in both autochthonous and allochthonous positions, for a review of ages and correlations see Cawood et al. (2007) and Kirkland et al. (2008b). In the Scandinavian Caledonides, detrital zircons from sedimentary units have been dated hitherto from allochthonous units in south-central Norway (Valdres; Bingen et al. 2005a, 2009), in the central Norwegian-Swedish Caledonides (Seve-Köli nappes; Ladenberger et al. 2009), and in the northernmost Norwegian Caledonides (Kalak Nappe Complex; Kirkland et al., 2006, 2007).

The Kalak Nappe Complex (KNC) has been assigned to the Upper Allochthon but has a debated origin. Recent work has postulated an exotic origin for the KNC, based on the fact that 850-690 Ma igneous intrusions dated within the allochthon are not found in the Fennoscandian autochthon (Kirkland et al. 2006, 2007; Corfu et al. 2007). However, palaeocurrent data from sediments in the lower part of the KNC favour a Fennoscandian source (Roberts 2007). As highlighted by Roberts (2007), the argument for an exotic origin of the KNC is based on negative evidence, i.e. the fact that igneous rocks of the appropriate age are not currently known from the autochthon. The Kvitenut and Revsegg units may provide insight into this argument, as they comprise metasedimentary rocks that correlate in depositional age with those in the KNC (<~980 Ma), and that are cross-cut by igneous units.

In the central Scandinavian Caledonides, the allochthonous rocks from bottom to top are: mylonitic granites and psammites, the Särv Nappes, the Seve Nappe Complex (SNC) and the Köli Nappes. These originate as the imbricated Fennoscandian basement, continental margin sediments, continent-oceanic transition zone, and Iapetus-derived oceanic terranes. The Dyrskard-Kvitenut-Revsegg allochthon can be correlated with the lower part of the sequence, comprising basement

slices and shallow marine to continental shelf deposits. The U-Pb detrital signatures recorded from the Kvitenut and Revsegg units are also comparable to metasedimentary units from the lower Seve nappe (Ladenberger et al. 2009), which has deposition <850 Ma, and peaks at 1000, 1400 and 1650 Ma.

In the Seve-Köli Complex, the Seve nappe units have reached granulite-facies metamorphism during Caledonian orogenesis (Claesson 1987), whereas the underlying Sarv and Offerdal nappes and the overlying Köli nappes are lower grade. This has lead to the ductile extrusion of the high-grade Seve Nappe Complex being compared to the channelised flow model for the Himalayan orogeny (Ladenberger et al. 2009). The Dyrskard-Kvitenut-Revsegg allochthons has similarities to the SNC, with the central Kvitenut complex preserving higher-grade metamorphism and migmatisation than the overlying Revsegg and underlying Dyrskard units. Further work is needed to elucidate whether these units were extruded in a large orogen-scale channel, or whether they were emplaced as separate nappe complexes at different times.

Metasedimentary units within Scotland correlate in age with the studied Kvitenut and Revsegg paragneisses. Detrital age patterns show some similarities; however, those in Scotland have been correlated with a Laurentian source (see Cawood et al. 2007). In the central Scandinavian Caledonides, sedimentary units from both the Lower and Middle Allochthons have been dated using detrital zircons (Bingen et al. 2005a; 2009). The zircon populations are similar to those dated here from the HRNC, and to those from the other regions discussed above, however, a population of grains at  $620 \pm 14$  Ma in the Lower Allochthon constrains an Ediacaran maximum age of deposition (Bingen et al. 2005a). Because the minimum age of deposition for the sedimentary units is not constrained, it is not known whether the Kvitenut and Revsegg Units correlate with this Ediacaran period of deposition, or with older Tonian (1000-850 Ma) deposits such as those in the Kalak Nappe Complex.

Distinguishing between a Laurentian and a Fennoscandian source is problematical, as the tectonothermal evolution of both continents is very similar throughout the Palaeo- to Mesoproterozoic. In a recently proposed model, post-Sveconorwegian sedimentation occurred in the North Atlantic region in the Asgard sea that formed by the clockwise rotation of Fennoscandia in relation to Laurentia (Cawood et al. 2010); the sedimentary successions were affected by tectonothermal events (Renlandian – 980-910 Ma and Knoydartian – 830-710 Ma), defining the Valhalla Orogen. Events in the Valhalla orogen are tectonically discrete from those in the Sveconorwegian orogen, as they formed in an external accretionary orogen as opposed to the interior Sveconorwegian orogen (Cawood et al. 2010). Gaining further knowledge of the

tectonothermal events that have affected the HRNC will be useful in constraining correlations between this exterior orogen with events that affected the interior of the Rodinia supercontinent.

Figure 8.8. (Top) Cumulative probability plots of detrital units within the HRNC (Revsegg and Kvitenut) compared with ages from the autochthonous basement within SW Fennoscandia (compilation from Bingen & Solli 2009). (Bottom) Age compilation of magmatic (black bars) and metamorphic/anatectic (grey bars) events within Scandinavian Caledonian terranes, compared with protolith ages determined in this study (dark grey boxes). Grey vertical bars represent the time periods of the main Sveconorwegian orogenic phase and Telemarkian continental growth (Bingen et al. 2008a). See Table 8.1 for compilation of age data.

### 8.8.2 Gothian-Telemarkian continental growth

In Fennoscandia, the autochthonous basement underlying the Caledonian nappes youngs to the southwest, with the crust being divided into Transcandinavian Igneous Belt (TIB) 1850-1700 Ma, Gothian 1700-1520 Ma, and Telemarkian 1520-1480 Ma terranes (Åhäll & Connelly 2008; Bingen et al. 2008a). Crystalline units within the allochthonous nappes have similar ages to the autochthonous basement that underlies them, for example in the Telemark Sector the HRNC comprises ~1500 Ma rocks overlying ~1500 Ma basement, and to the north of this, the Jotun Nappe comprises 1650 Ma rocks that likely overlie 1650 Ma Gothian crust (Lundmark & Corfu 2008). The original position of the crystalline nappe units was likely to the west/northwest of their current position, and outboard of the current coastline. Thus, the southwesterly younging age pattern of the crust likely existed prior to any Caledonian orogenesis, and extended out to several hundred kilometres offshore of the current coastline (Figure 8.9).

Figure 8.9. The postulated original position of Middle Allochthon nappe units in the southern Scandinavian Caledonides is shown as grey ellipses. The dashed arrows show the likely post-Sveconorwegian shedding of detritus from the Fennoscandian continent into basins that formed sedimentary units in the upper parts of the Middle Allochthon (e.g. Kvitenut and Revsegg units). HRNC, Hardangervidda-Ryfylke Nappe Complex; JNC, Jotun Nappe Complex; DN, Dalsfjord Nappe; LN, Lindas Nappe (modified from Lundmark & Corfu 2008).

### 8.8.3 Sveconorwegian orogeny in SW Norway

Bingen et al. (2008c) divide the Sveconorwegian orogeny into a time-frame of four periods, based on events that occur throughout SW Fennoscandia. The Arendal Phase (1140-1080 Ma) is related to the collision between Telemarkia and the Idefjorden terrane, forming the highly tectonised Bamble and Kongsberg terranes, with the only effect of this in southwest Norway being continental sedimentation resulting from localised uplift (Bingen et al. 2008c). The Agder Phase (1050-980 Ma) corresponds to the main orogenic phase with continent-continent collision, and crustal thickening that peaked at ~1035 Ma (Bingen et al. 2008c). In Telemarkia the ~1050 Ma Feda Suite is related to either east-dipping subduction prior to continent-continent collision, or to melting of older calcalkaline crust during crustal thickening (Bingen & van Breemen 1998; Bingen et al. 2008c; Slagstad et al. 2008). The ~1062 Ma age for the Dyrskard supracrustals, and their likely setting in an extensional basin above a supra-subduction zone, is much more compatible with a continentalarc origin rather than a crustal thickening origin for the Feda granitoids.

# **8.9** Conclusions

U-Pb geochronology of allochthonous units within the HRNC has shown that the units are much younger than previously interpreted from Rb-Sr dates. The basal allochthon contains an intermediate igneous unit dated at 1493 ± Ma, interpreted to be a locally derived thrust slice of basement. In the Storhei Nappe, a granitic gneiss is dated at ~1500 Ma, and features Sveconorwegian metamorphism at 1020 Ma. Thus, Telemarkian age crust likely extended much further northwest than the current coastline prior to Caledonian shortening. The Dyrskard Unit is dated at ~1062 Ma, and is interpreted as a supracrustal sequence deposited in a shallow basin in a supra-subduction setting. This adds evidence to the argument that the early-Sveconorwegian history included continental arc magmatism (Feda suite) at ~1060-1040 Ma. The Kvitenut and Revsegg units contain sedimentary paragneisses deposited after the main Sveconorwegian orogenic phase <950-980 Ma. Further work is needed to establish the minimum age of deposition. Cross-cutting units in these allochthons may correlate with those in the Kalak Nappe Complex, aiding the debate on the origin of this allochthonous complex.

# Discussion

## 9.1 Crustal evolution in the Telemarkian (1.52-1.48 Ga) period

Based on their petrology, petrography and intrusive-relations, the orthogneisses exposed in the Suldal Sector are thought to represent mid- to upper-crustal, hypabyssal and supracrustal igneous rocks, intercalated together during the evolution of a mature volcanic arc complex (Chapter 2). This interpretation is backed up by the whole-rock geochemistry of the orthogneisses, which exhibit typical calc-alkaline subduction-related signatures (Chapter 3). This arc is referred to as the Suldal arc; U-Pb geochronology of various lithologies suggests that it was active from ~1475 to 1521 Ma (Chapter 3).

The geochemistry of the Suldal arc is indicative of continental crust that is thickened relative to typical island arc crust, suggesting a mature island arc or continental arc setting. In continental arcs, magmatism may be dominated by recycling of pre-existing crust as opposed to addition of new crust (i.e. mantle addition). Coeval continental-rift magmatism in the adjacent Telemark Sector involved voluminous magmatic underplating, and felsic magmatism derived from crustal anatexis, suggesting a significant thickness of lithosphere must have existed prior to 1.5 Ga. Zircon inheritance is often used to infer older deep crust; inheritance is almost non-existent in Telemarkian magmatism (see Chapter 3), meaning that such an inference cannot be made based on the zircon data.

As discussed in Chapters 4 and 5, Andersen et al. (2001, 2002b, 2004a, 2007b, 2009b), Andersen & Griffin (2004) and Pedersen et al. (2009) advocate the existence of a pre-1.5 Ga deep crust throughout southwest Fennoscandia; they base this hypothesis on scant inherited zircons in younger <1.5 Ga intrusions, low  $\epsilon$ Hf in a few <1.5 Ga zircons, and Nd and Sr isotopes in 1.5-1.6 Ga and <1.5 Ga granitoids that depart from a depleted mantle signature. The Hf-O data presented in Chapter 4 confirms that a component older than 1.5 Ga and comprising a high- $\delta^{18}$ O signature (e.g. weathered sediments), made a contribution to the 1.5 Ga Suldal arc magmatism. The addition of such a component did not occur purely by mantle recycling, i.e. contamination from subducted sediments, but must have involved some recycling of this older component within the crust (intracrustal recycling). However, intracrustal recycling of an older sedimentary component does not prove the existence of an extensive older deep crust; intracrustal recycling requires burial and remobilisation of older sediments, which can occur via a number of processes, such as closure of back-arc basins and underthrusting at subduction margins.

Combining all of the evidence, it is suggested that the Suldal arc and its ensialic back-arc rift (the Rjukan Rift in Telemark), developed on an attenuated continental margin which comprised a degree

of older Gothian-aged (>1600 Ma) sediments; although, an origin on a rifted continental fragment cannot be discounted.

### 9.1.1 'Indigenous' or 'Exotic' Telemarkia

Traditionally, the crust of the SSD was interpreted to have grown by successive westward accretion (e.g. Berthelsen 1980; Gaál & Gorbatschev 1987). Later on, the crust west of the Oslo rift (e.g. Telemarkia) was inferred to be a crustal block >1.65 Ga in age, based on limited zircon U-Pb ages (Ragnildstevt et al. 1994; Schärer et al. 1996; Birkeland et al. 1997). This led to a number of suggestions that the crust west of the Oslo rift formed a separate continental block or 'proto SW-Norway'; this block may have accreted between 1.58 Ga and 1.5 Ga (Åhäll et al. 1998, 2000, or during the Sveconorwegian orogeny (Cornell & Austin Hedgart 2004). The zircon evidence can now be regarded as inconsequential, because the U-Pb ages are interpreted to have a detrital origin (Bingen et al. 2005b). The crust exposed at the surface of the SSD has a general east to west younging pattern, which can be inferred to represent a younging of the crustal domains, and therefore a possible origin as sequentially accreted terranes. However, as pointed out by Pedersen et al. (2009), models which are based on the age of exposed crust, in some cases fail to account for the age of the deep crust. Conversely, it is argued that models using in-situ U-Pb-Hf data to account for the age of the deep crust, in some cases *explicitly* imply features such as extensive Palaeoproterozoic crust at depth, where the data only indicate that such crust may exist (Pedersen et al. 2009; Andersen et al. 2009b).

Formation of the Suldal arc is inferred to have occurred above an east-dipping subduction zone (see Chapter 4). Calc-alkaline granitoids formed in the Idefjorden terrane as young as 1.49 Ga (Pózer Bue 2008), and are likely related to the youngest expression of east-dipping subduction that formed the Hisingen Suite continental arc (Åhäll & Connelly 2008). The coexistence of this arc with the 1.5 Ga Suldal arc in Telemarkia can be explained by two models: 1) where the arcs formed above the same subduction zone, and were later translated by strike-slip faulting to their current position, and 2) where two different subduction zones produced two contemporaneous arcs. The first model is compatible with the strike-skip terrane model advocated by Andersen et al. (2004a), de Haas et al. (1999) and Bingen et al. (2001b), and originally proposed by Torske (1985). The second model is consistent with an exotic microcontinent model for Telemarkia (Bingen et al. 2005b), but is suggested to be incompatible with the isotope data (Andersen et al. 2001, 2002b, 2004a, 2009b).

There is some limited structural evidence for the terrane displacement model, including coeval sinistral strike-slip and reverse dip-slip sense of shear on the mylonite zone, characteristic of a transpressive tectonic regime (Stephens et al. 1996), and early SE-directed movements that were later partitioned into sinistral strike-slip movements (Park et al. 1991). U-Pb ages of detrital zircons

in various metasedimentary units also provide evidence for this model. Metasedimentary units deposited during the Telemarkian period (those that are >1.48 Ga), contain abundant Palaeoproterozoic zircons, particularly correlating in age with the ~1.75-1.9 Ga Transcandinavian Igneous Belt; they also contain Archaean zircons. There is a relative lack of zircons in the 1.7-1.6 Ga age bracket that correspond to the age of the crust to the east of Telemarkia; such zircons are abundant however in metasedimentary units within the Idefjorden Terrane. This suggests that the Telemarkia terrane was proximal to TIB and Svecofennian age parts of the Fennoscandian continent (or another continent of similar age), and was not shielded from such detritus by the Idefjorden terranes; the detrital zircon data are therefore compatible with a strike-slip displacement model (see Figure 9.1).

Figure 9.1. Strike-slip terrane displacement model, showing major lithotectonic domains and their relative motion (after Bingen et al. 2001b).

Whether the Telemarkia terrane is 'indigenous' or 'exotic' can be put down to semantics. For example, Japan has an origin as a rifted fragment of the Eurasian continent (e.g. Tamaki 1995); since rifting it has suffered a different history to that of the Eurasian continent, but after future closing of the Pacific Ocean (e.g. Maruyama et al. 2007) Japan will be accreted back onto Eurasian continental crust. After this juxtaposition, a study of the isotopic characteristics of the Japanese lower crust, and that of the adjacent Eurasian lower crust, may find very similar isotopic signatures due to their pre-rifting mutual history. The isotopic similarities of the lower crust could be used to

Figure 9.2. Compilation of detrital zircon U-Pb data for SW Fennoscandia, from Knudsen (1997), Åhäll et al. (1998), de Haas et al. (1999), Bingen et al. (2001b, 2002, 2003), Andersen et al. (2004a, 2004b),

interpret an 'indigenous' origin for the Japanese terranes, or, the contrasting characteristics of the upper crust could be used to interpret an 'exotic' origin.

Andersen et al. (e.g. 2004a, 2009b) use the isotopic signatures of magmatic rocks across SW Fennoscandia to interpret an indigenous origin for Telemarkia. Cornell & Austin Hedgardt (2004) use the contrasting ages of granites exposed at the surface across the Mylonite Zone to interpret an exotic origin for both the Idefjorden and Telemarkia terranes. The model described in the next section aims to satisfy all of the data.

### 9.1.2 A retreating accretionary orogenic model

Combining all of the previous geochronology and geochemical considerations, Ahäll & Connelly (2008) present a model for the evolution of SW Fennoscandia, from formation of the TIB to the end of the Gothian period (1.52 Ga). In their model, the various lithotectonic domains represent nearcontinuous oceanward-stepping (westward) crustal growth along a long-lived subduction zone; changes from continental to oceanic arcs are attributed to advance and retreat of Fennoscandia relative to the subduction trench. This geodynamic setting is consistent with a retreating accretionary orogen (Cawood et al. 2009); the advance and retreat of a subduction trench in relation to the continent is termed tectonic switching, and is an efficient way of producing continental crust (Collins 2002; Kemp et al. 2009). In their model, Åhäll & Connelly (2008) do not specifically refer to the nature of the lower crust, or the radiogenic isotopic characteristics of the crustal domains; their continental growth calculations however, do imply a relatively juvenile nature throughout. Åhäll & Connelly (2008) end their model at 1.52 Ga, based on the assumption that this is the age of the youngest subduction-related magmatism recorded in the Gothian terranes, but suggest that Telemarkia may represent a younger continuation of this oceanward-stepping westward crustal growth. The conclusions from this study indicate that their suggestion is consistent with the data, and thus it is postulated that the growth of Telemarkia is related to a long-lived subduction zone that also produced the Gothian terranes, and was initiated during TIB continental arc magmatism. As pointed out by Ahäll & Connelly (2008), Telemarkia may have been originally located further north along the margin of Fennoscandia (see Figure 9.1), but a southern continuation of Telemarkia or another crustal segment likely existed in its place, and was subsequently translated elsewhere; Telemarkia thus provides a proxy for the crust that existed outboard of the Idefjorden terranes.

The following issues have already been raised: 1) is Telemarkia indigenous or exotic to Fennoscandia? and 2) does Telemarkian growth represent recycling of older Fennoscandian crust or is Telemarkia a juvenile terrane? In the model of a retreating accretionary orogen, these issues are answered in the following way: 1) Telemarkia is built on attenuated continental crust of Fennoscandian origin, this explains the similarities in radiogenic isotopic character of the deep crust across the region; however, it is not unconceivable that the Telemarkian segment of crust rifted

away from the Fennoscandian continent, thus forming a continental ribbon (or microcontinent). Jostling between this and other terranes during the Sveconorwegian orogeny, means the Telemarkia block could be regarded as 'exotic' according to some terrane criteria, but its overall origin is with that of a SW Fennoscandian accretionary orogen, thus an 'indigenous' origin is preferred. 2) Because Telemarkia was built on a thin continental substrate, the arc magmatism involved a degree of recycling of this older continental crust; Telemarkia is therefore not considered to be an 'accreted juvenile arc'. Conversely, Telemarkian magmatism is not likened to Andean-type settings where thick continental crust exists and continental recycling dominates over mantle addition; a preferred analogue for Telemarkia is that of modern arcs in the western Pacific that originate as rifted continental ribbons, such as Japan.

Figure 9.3. Simplified model of a retreating accretionary orogen to explain the westward growth of continental crust in SW Fennoscandia in various arc settings. The continuous east-dipping subdcution zone and attenutuation of the continental margin means that the isotopic characteristics of the deep crust are retained for large horizontal distances. TIB = Transcandinavian Igneous Belt, SLM = Stora Le Marstrand, black hatching refers to crust of late-Palaeoproterozoic age. (Modified from Åhäll & Connelly 2008).

# 9.2 Crustal evolution in the Sveconorwegian (1.06-0.92 Ga) period

New U-Pb ages (Chapter 3) show that the Storlivatnet plutonic complex in the Suldal Sector does not fall into the group of post-collisional Sveconorwegian granites, as it formed much earlier; U-Pb

ages from the plutonic complex date intrusions at  $1039 \pm 15$ ,  $1047 \pm 7$  and  $1069 \pm 9$  Ma. Deformation of the pluton is inferred to have occurred between  $1047 \pm 7$  and  $1069 \pm 9$  Ma; although this provides evidence for Sveconorwegian deformation within the region, the effect of this orogeny on the U-Pb systematics within the basement rocks is minimal (see Chapter 3). Inheritance of >1.5 Ga crust was not recorded in Sveconorwegian rocks of this study.

Early to pre-Sveconorwegian granitoids feature both I-type and A-type geochemistry, postcollisional granites are all A-type; the origin of these two suites can be explained by changes in water content (and oxygen fugacity) in the melting region (see Chapter 6). A supra-subduction zone setting is favoured for the pre-collisional granites; this setting provided hydrous conditions for formation of I-type magmas. Subsequent granite suites formed in a collisional setting with crustal thickening, and then a post-collisional setting with associated crustal thinning. Throughout these different geodynamic regimes the heat flux that is required to produce granitic magmatism will have changed, however, Hf-O data suggest that the magma source stayed the same (see Chapter 6). The magma source advocated for the Sveconorwegian magmatism involved a large contribution from 1.5 Ga crust, and a smaller contribution from mantle-derived material that is ~1.2 Ga or younger. The magma source was mafic lower crust that had isotope and geochemical characteristics imparted from previous magmatic episodes. Partial melting and fractionation of this mafic lower crust produced parent magmas that then evolved to granitoid intrusions.

The conclusions of this study confirm that the Sveconorwegian period largely involved recycling and remobilisation of pre-existing continental crust, as opposed to addition of new crust.

# 9.3 The 'interorogenic' period

The period after Telemarkian continental growth and before Sveconorwegian reworking, i.e. 1.46-1.06 Ga, features intermittent and generally localised periods of magmatism and sedimentation. Magmatic activity is dominated by mafic volcanism, but also includes felsic volcanism which is likely a result of crustal anatexis produced by heat from mafic intrusions. In Telemarkia, volcanism is typically associated with sedimentation in rift basins, whereas in the Idefjorden and Eastern Segment terranes, magmatism is associated with crustal lineaments or mafic dyke swarms (see Chapter 7). Both the formation of extensional basins and the intrusion of mafic dyke swarms, can be related to inboard effects of a convergent margin existing to the west of the present-day coastline (Brewer et al. 2002; Brewer et al. 2004; Söderlund et al. 2006; Chapter 7); although the 1.2 Ga Tromøy block is the only preserved arc crust of this age (Knudsen & Andersen 1999). This interpretation means that convergent margin activity is recorded in SW Fennoscandia from ~1.8 Ga (Transcandinavian Igneous Belt) to ~1.05 Ga (Feda Suite; see Chapter 6). It is also worth noting that 1.69-1.50 Ga A-type Rapakivi suites in Sweden and Finland have also been interpreted as distal affects of convergent margin activity on the southwestern Fennoscandian margin; this is based on a temporal and spatial trend for the A-type suites that matches that of westward arc magmatism in the Idefjorden and Telemarkian terranes (Åhäll et al. 2000). Some ~1.85-1.75 Ga A-type suites in Finland have post-collisional tectonic settings advocated, i.e. magmatism related to lithospheric thinning after crustal relaxation (Eklund et al. 1998; Väisänen et al. 2000; Kurhila et al. 2010). In accepting the above interpretations, it is worth pointing out that for a 1 Gyr period (~1.8 to ~0.8 Ga) all tectonothermal, magmatic and sedimentary events in Fennoscandia can be in some way related to convergent margin tectonism, and thus, there is no call for any deep-seated mantle anomalies to explain any particular events.

### 9.3.1 The Hallandian-Danopolonian event

The term Hallandian was coined by Hubbard (1975) for metamorphism, anatexis and magmatic events around ~1.4 Ga in southwest Sweden. Christoffel et al. (1999) later defined the Hallandian as a thermo-magmatic event in the 1.44-1.38 Ga period. The term Danopolonian was used by Bogdanova et al. (2001) for tectonothermal events in the East European Craton between 1.5 and 1.4 Ga, and was related to a possible collisional orogeny between Baltica and another continent (probably Amazonia). More recently the informal term Hallandian-Danopolonian has emerged, and can be ascribed to any tectonothermal event in the 1.46-1.38 Ga period.

Ages between 1.46 and 1.42 Ga for new zircon growth/recrystallisation have been reported in veined gneisses in the south of the Eastern Segment (Christoffel et al. 1999; Söderlund et al. 2002). Magmatism in the Eastern Segment includes granitic to monzonitic intrusions ~1.4 to 1.36 Ga in age (Åhäll et al. 1997; Andersson et al. 1999, 2002; Christoffel et al. 1999; Möller et al. 2007); these include dehydrated charnockitic granites. Dehydration of a localised zone (<10m) of pre-1.46 Ga granitoid has been dated at 1397  $\pm$  4 Ma (Rimša et al. 2007). On Bornholm Island to the east of the Eastern Segment, granites and orthogneisses have crystallisation ages from ~1475 to 1445 Ma (Zarinš & Johansson 2008); an east-west trend is interpreted to have formed synchronously with the magmatism, and titanite ages are coeval to slightly younger than the magmatic ages suggesting slow-cooling.

In the Idefjorden terrane to the west of the Eastern Segment, there are bimodal granite-gabbro intrusions dated at ~1.5 Ga (Åhäll & Connelly 1998), ~1.46 Ga dolerite dyke swarms (Hageskov 1997; Åhäll & Connelly 1998), and intermittent granite magmatism at ~1.34 to 1.25 Ga (Persson et al. 1983; Piontek et al. 1998; Austin Hegardt et al. 2007). No well constrained 1.46-1.42 Ga zircon growth has been recorded from the Idefjorden terrane; the lack of Hallandian-Danopolonian metamorphism in the Idefjorden terrane is one of the arguments used for its exotic origin (Andersson et al. 2002; Cornell & Austin Hegardt et al. 2004).

Brander & Söderlund (2008) note that in the Hallandian-Danopolonian period there is a predominance of mafic intrusions in the north and felsic intrusions in the south, and interpret this as possibly being related to distal effects of an orogeny in the south. However, some of these mafic intrusions can also be interpreted as distal effects of convergent margin tectonism in the west (see Chapter 7; Söderlund et al. 2005). The Hallandian-Danopolonian event has not affected the Telemarkia terrane, and thus could be assumed to have only affected inboard terranes. However, it is possible that the Hallandian-Danopolonian did affect terranes to the west of Idefjorden, but that these terranes have now been replaced by the unaffected Telemarkia terrane, which until the Sveconorwegian was located further north along the Fennoscandian margin (see Figure 9.1).

Contemporaneous with 1.5-1.6 Ga arc magmatism and 1.46-1.38 Ga tectonothermal events in the southwest of Fennoscandia, the central and eastern parts of the East European Craton were host to rifting events; these can be interpreted as both back-arc responses to Hallandian-Danopolonian convergence, and to abortive break-up of the East European Craton (see Bogdanova et al. 2008 and references within).

# 9.4 A tectonic synthesis

Figure 9.4 depicts the building of Fennoscandia during the Proterozoic; the pre-1.85 Ga configurations are modified from Korja et al. (2006) and Lahtinen et al. (2009). During the period between 2.0 Ga and 1.8 Ga, various Archaean continental blocks amalgamated in collisional orogenies (Lapland-Savo, Fennia, Svecobaltic and Nordic orogens; Lahtinen et al. 2009); caught up within these orogenic belts were juvenile Palaeoproterozoic arc and microcontinental blocks. As well as collisional orogenies, the 2.1-1.8 Ga period involves retreating (Tersk, Kittilä, Savo and Häme) and advancing (Tampere, Bergslagen and TIB1) accretionary orogenic belts (Lahtinen et al. 2009). By 1.8 Ga, the Palaeoproterozoic and Archaean domains were amalgamated into a stabilised craton; Sarmatia and Volgo-Uralia had also amalgamated by this time to form the East European Craton (Bogdanova et al. 2008).

Subduction on the south and west margins of Fennoscandia that formed the TIB1 continental arc, marks the beginning of a long-lived retreating accretionary orogen. This accretionary belt was active until Sveconorwegian continent-continent collision at ~1.05 Ga. Crustal additions related to this accretionary belt are ~1.75 to ~1.48 Ga in age (Gothian and Telemarkian). The period between 1.48 and 1.05 Ga involved little net crustal addition; the preserved crust was likely in back-arc and inboard positions relative to the convergent margin, and outboard juvenile crust that may have been produced during this time has likely been lost via both subduction erosion, and terrane displacement.

Subduction and back-arc rifting in the Lapland-Kola area, westwards subduction under the Keitele mc and Norbotten mc, and subdcution to the NE under the Norbotten mc and east under the Keitele mc.

Beginning of the Fennian orogeny. As a result of locking of northward subduction under the Keitele mc, the southern ocean is consumed by subduction to the south under the combined Häme island arc and Bergslagen mc. After amalgamation of the Bothinan mc, another subduction zone is formed at its southern margin.

The subduction zone migrates oceanward relative to Fennoscandia. TIB 2/3 arc rocks form in an extensional continental arc.

Archaean and Palaeoproterozoic crust has formed and is largely stabilised. Subduction initiates to the north and east, large-scale extension takes place in the hinterland, and Fennoscandia amalgamates with Sarmatia.

Overall the subdcution zone is migrating oceanward, but periodic trenchward movement accretes Gothian and Telemarkian arc terranes to Fennoscandia. By 1.5 Ga most of the Fennoscandian crust is stabilised.

Figure 9.4. A schematic model for the amalgamation of Fennoscandian continental crust during the Palaeo- to Mesoproterozoic (modifed from Korja et al. 2006; Lahtinen et al. 2009). mc = microcontinent, IA = Inari Area, TT = Tersk Terrane, LGB = Lapland-granulite Belt, UGT + Umba Granulite Terrane, GAB = Göteborg-Åmål Belt, TIB = Transcandinavian Igneous Belt.

Figure 9.5. The distribution of metamorphism, magmatism and sedimentary basins during the Sveconorwegian orogeny (modified from Bingen et al. 2008c; Bogdanova et al. 2008).

Figure 9.5 depicts the Sveconorwegian orogeny in Fennoscandia, modified from Bingen et al. (2008c) and Bogdanova et al. (2008). Modifications to the model include the addition of the 1.07-1.04 Ga Storlivatnet pluton, and an east-dipping subduction zone that produced the >1.04 Ga granitoids.

# 9.5 Reading the isotope barcode

The tectonic model discussed in the previous section features a retreating accretionary orogen that was active from ~1850 Ma to 1050 Ma. The period of accretion was concluded by ~1030 Ma with a major continent-continent collision and reworking and reorganisation of terranes. The onset of this accretionary orogen is defined by an active continental margin that reworked previously formed crust (the Transcandinavian Igneous Belt); accretionary orogenesis also occurred prior to the TIB continental arc event, but the TIB allows for a convenient separation between >1.85 Ga Svecofennian and <1.8 Ga Gothian to Sveconorwegian events.

In the Gothian-Telemarkian orogen, the oldest (and exposed) upper crust youngs to the west, from ~1750 Ma in the east (Eastern Segment) to ~1480 Ma in the west (Suldal/Rogaland). Various episodes of arc magmatism have been recognised from combined field, geochemical and geochronological data, including Horred (1.66 Ga), Göteborg-Åmål (1.61-1.59 Ga), Hisingen (1.59-1.52 Ga), and Telemarkian (1.52-1.48 Ga) (Åhäll & Connelly 2008 and references within; Chapters 2 to 5). Back-arc and fore-arc sequences with arc-dominated greywacke sediment are generally restricted to the Idefjorden terrane, but are also found in the Bamble and Kongsberg collisional terranes. Younger extensional basins with continental or shallow sedimentation are found across the Telemarkia terranes, and magmatism that is not clearly arc-related occurs in various discrete episodes throughout the discussed time period (see Chapter 7 and section 9.3).

The Lachlan orogen in SE Australia is a younger example of a retreating accretionary orogen, where the coupling of arc and back-arc, and magmatic, metamorphic and sedimentary processes are well-documented (e.g. Collins 2002; Kemp et al. 2009; Foster et al. 2009). One method of continental crust formation in this orogen is the formation of S-type granites during closure of backarc basins. These granites form during a compressional state of the orogen, and have the most evolved Nd and Hf signatures relative to other suites in the orogen (Kemp et al. 2009). During the maximum extensional state of the orogen, A-type granites with the most depleted Hf and Nd signatures are produced (Kemp et al. 2009). I-type granites occur during the initial extensional phases in back-arc and fore-arc settings, and have mixed mantle and sedimentary isotope signatures (Kemp et al. 2007). The temporal variation in the isotopic signature of different granitoid suites is correlative with the geodynamic setting of magmatism. In its simplest terms, the amount of mantle addition to magmatism increases during the maximum extensional state of the orogen; this may reflect a variety of processes such as intrusion into thinned crust and/or intrusion along extensional structures, as well as a decrease in sediment-subduction or subduction-erosion. In the Lachlan orogen, the thickness of crust is postulated as the underlying cause of varying mantle/crustal contributions (Kemp et al. 2009).

Whereas the Lachlan orogen features marginal basins and large volumes of turbiditic sediments (Foster et al. 2009), the orogen studied here features voluminous arc crust, with limited volume of turbidites. Kemp et al. (2009) suggest such features are related to a quasi-stationary subduction zone, such as the Canadian Cordillera. In the Lachlan orogen the crust has been shortened by ~75% (Foster et al. 2009), in the Fennoscandian orogen, it is likely to be less than 50% given the lack of ocean basin formation. This difference in extension has produced the variance in volume of sediment versus igneous crust. The Fennoscandian orogen is also eroded to a deeper crustal level, implying that a greater volume of supracrustal material may have existed originally.

#### 9.5.1 Source versus time

Figure 9.6a shows a compilation of published and new Hf isotope data for SW Fennoscandian autochthonous basement domains. The data fall into clusters that from oldest to youngest are TIB1 and TIB2/3 arc-related units; Göteborg-Åmål, Hisingen and Telemarkian arc-related units; ~1.3-1.1 Ga interorogenic units; and 1.06-0.92 Ga Sveconorwegian granitoid units. Ranging from ~1.6 to 0.92 Ga are mafic intrusions that intrude terranes east of the Oslo Rift. The inter-orogenic rocks likely formed in a supra-subduction zone setting (see Chapter 7), particularly those in the Setesdalen region (Pedersen et al. 2009). Figure 9.6b shows averages of the data using 25 Myr bins; this enables the general trend in  $\epsilon$ Hf to be visualised.

TIB 1 and TIB 2/3 magmatism can be related to continental arc magmatism that involved a large proportion of recycling of pre-existing Svecofennian crust. The switch to arc magmatism forming the Göteborg-Åmål Belt (GAB) and Hisingen Suite (Åhäll & Connelly 2008), involved a change to a greater degree of mantle input; this change is interpreted to reflect slab rollback so that magmatism intrudes thinner crust, and that magmatism is more distal to the continent so that the volume of older subducted sediment is decreased. Between 1.6 and 1.5 Ga there were multiple episodes of back-arc/fore-arc sediment deposition (Stora Le-Marstrand formations), and accretion of arc-derived blocks (Åhäll & Connelly 2008); however, the data cannot pick out differences in mantle input at this timescale. During the following Telemarkian period, arc magmatism featured a slightly decreasing apparent mantle input. The Telemarkian arc were likely built upon the same crust that the GAB and Hisingen arcs were built upon, and features a slightly increased amount of crustal reworking.

The interorogenic period is represented by units within central and southern Telemarkia; this period begins with a relatively dominant mantle signature, which then decreases until ~1.22 Ga. At ~1.2 Ga there is another change to a greater mantle input, which again decreases over time. These perturbations in  $\epsilon$ Hf over time can be related to periods of maximum slab retreat at ~1.35 and ~1.2 Ga, such that magmatism occured in extensional settings or in thinned crust, where crustal

assimilation was limited. There were no perturbations relating to increased mantle input in the Sveconorwegian period, suggesting that the magmatism involved significant reworking of crust.

Mafic intrusions do not fall on the depleted mantle trend; this can be explained by two models, 1) where the mafic intrusions result from melting of older mafic lower crust, and therefore have evolved  $\epsilon$ Hf signatures, or 2) where the mafic intrusion result from enriched mantle domains. The latter was favoured by Söderlund et al. (2005), who postulated enrichment of lithospheric mantle via previous subduction episodes; however, some of the contemporaneous arc-related granitoids have more depleted signatures suggesting that a depleted mantle reservoir must have been available. Either the mafic intrusions and arc-related granitoids tapped different mantle sources, or the mafic intrusions comprise a degree of crustal anatexis or assimilation. Most of the mafic intrusions broadly correlate in time with inferred periods of extension; the ~0.95 Ga mafic intrusions can be explained by lithospheric thinning during orogenic collapse.

Perturbations in the  $\epsilon$ Hf trend to increased mantle input can largely be explained by slab retreat, extensional tectonics, and an increase in mantle addition to magmas; perturbations away from the mantle curve can be explained by compressive or collisional tectonics, and reworking of preexisting crust. Therefore in its simplest terms, these trends can be interpreted in the context of continental growth versus continental recycling (Figure 9.6b).

### 9.5.2 Comparison with other evidence

The temporal isotope trend provides a barcode of inferred compressional and extensional events that can be correlated with geodynamic events interpreted from alterative evidence; such evidence is documented below:

### 9.5.2.1 Compressive phases

Pre-1.65 Ga deformation in the Idefjorden and Eastern Segment is poorly constrained. As discussed previously, some deformation may be related to Hallandian-Danopolonian events. Owing to the existence of sedimentary units within the Idefjorden terrane, 1.6-1.5 Ga events are well-constrained compared to other time periods.

Deformation of the Horred arc, which is related to its accretion onto the Fennoscandian continent, is older than a cross-cutting granite at  $1578 \pm 7$  Ma; with the switch from island arc to continental arc magmatism at 1634 Ma suggesting accretion by this time (Åhäll & Connelly 2008). Volcano-sedimentary units within the Amal formation, of which a rhyolite is dated at  $1631 \pm 3$  Ma, contain source material from an adjacent granite dated at 1634 + 3/-2 Ma, suggesting rapid unroofing of a magmatic arc at 1.63 Ga (Åhäll & Connelly 2008). A sandstone unit with 1.62 to 1.59 Ga and a few older zircon grains is suggestive of closure of Göteborg-Åmål basins by this time (Åhäll &

Connelly 2008). Deposition and deformation of SLM 1 rocks is constrained to be younger than  $1591 \pm 8$  Ma by the youngest detrital zircon (Åhäll et al. 1998), and older than  $1587 \pm 3$  Ma based on a cross-cutting intrusion (Connelly & Åhäll 1996; Åhäll et al. 1998. Deposition of SLM 2 rocks is bracketed by the youngest detrital zircon to be <1.56 Ga, with cross-cutting intrusions at  $1545 \pm 5$  Ma and  $1546 \pm 7$  Ma suggesting accretion by this time (Åhäll & Connelly 2008). Regional migmatisation related to accretion of SLM 2 rocks is estimated at 1.54 Ga from U-Pb data on zircon rims (Åhäll & Connelly 2008). Åhäll & Connelly (2008) distinguish three phases of Hisingen magmatism, at 1.59-1.56 Ga, 1.56-1.55 Ga, and 1.55-1.52 Ga; the youngest phase truncates fabrics in the earlier phases. Deformation is bracketed between  $1563 \pm 2$  and  $1558 \pm 2$  Ma, and between  $1555 \pm 2$  and  $1553 \pm 2$  Ma (Connelly & Åhäll 1996; Åhäll & Connelly 2008) from deformed host rocks and post-kinematic dykes.

Zircon growth at ~1.46-1.42 Ga in Eastern Segment gneisses suggests a high-grade compressive event (see 9.3.1); however such an event is not recorded in the terranes that the ɛHf data are derived from. Deformation is not recorded after this event until the Sveconorwegian period. At ~1140 Ma high-grade metamorphism is attributed to collision between the Telemarkia and Idefjorden terranes, and formation of the Bamble and Kongsberg tectonised terranes (Bingen et al. 2008c). At ~1100-1080 Ma high-grade metamorphism propagated locally into the Idefjorden terrane; the main continent-continent collision phase with associated regional metamorphism occurred between 1050 and 980 Ma (Bingen et al. 2008c).

### 9.5.2.2 Retreating phases

Evidence for slab retreat could be interpreted in the form of extensional basins; within SW Fennoscandia these include: Stora Le Marstrand 1 (~1.59 Ga ), Stora Le Marstrand 2 (~1.55 Ga), the Rjukan Rift (~1.51 Ga), the Sæsvatn-Valldall Belt (~1.26-1.21 Ga), and formations within the Sveconorwegian Supergroup (1.19-1.14 Ga). The mafic intrusions at ~1.6, ~1.56, ~1.46, ~1.27, ~1.22, and ~0.95-0.97 Ga (Söderlund et al. 2005), can also be interpreted in the context of extensional phases.

In general, major compressional phases (high-grade metamorphism) correlate with gaps in the magmatic record, indicating a lack of magma production during these periods. Minor compressional phases, such as those between 1.6 and 1.5 Ga, do not have a resolvable affect on the isotope trend. The ages of extensional basins and mafic intrusion correlate fairly well with the slab retreat phases inferred from the isotope trends. The 1140-1080 Ma magmatic gap (that was previously recognised by Bingen et al. 2008c) correlates with the interpreted collision between Telemarkia and Idefjorden; this would explain the lack of magmatism in this central region of SW Fennoscandia. The lack of magmatism on the western margin of the region however, is interpreted to reflect a compressive period where previously formed crust was removed via subduction erosion; this can be used to

partly explain the lack of 1.3-1.14 Ga arc crust to the west of Telemarkia, which would correlate with the back-arc basins preserved within Telemarkia.

Figure 9.6. A) Compilation of  $\varepsilon$ Hf<sub>(initial)</sub> zircon and whole-rock data from units with igneous protliths within SW Fennoscandia, plotted versus time (Ma). DM is depleted mantle of Griffin et al. (2000); reference lines are showing evolution of crust with Lu/Hf = 0.015. B) All  $\varepsilon$ Hf<sub>(initial)</sub> data averaged at 25 Ma bins. C) Compilation of <sup>207</sup>Pb/<sup>206</sup>Pb zircon ages from various time periods within SW Fennoscandia, shown as cumulative probability plots. Grey bars represent the range of magmatic ages for each period.

### 9.5.3 Zircon Inheritance

Zircon inheritance has been repeatedly discussed within this study; in Figure 9.6c, a compilation of zircon  $^{207}$ Pb/ $^{206}$ Pb ages for different age bracketed periods is shown. The periods interpreted as reflecting continental arc magmatism are the GAB and Hisingen, these feature a greater proportion of older zircons than the TIB 2/3 and Telemarkian periods which are interpreted to reflect magmatism on attenuated continental crust in extensional settings. The lack of inheritance in the 1100-1320 Ma interorogenic units is compatible with their largely juvenile origin; whereas the abundance of ~1.5 Ga zircons in Sveconorwegian units is compatible with them involving a large proportion of crustal recycling (see Chapter 6). Thus, the interpreted geodynamic settings of these periods are compatible with the pattern of zircon inheritance.

# 9.6 Supercontinents and global correlations

## 9.6.1 A global accretionary orogen?

The Proterozoic history of other continents is briefly discussed to examine the extent of 1.8-1.0 Ga accretionary orogens.

### 9.6.1.1 Laurentia

Similarities between the Late Palaeoproterozoic to Mesoproterozoic history of Fennoscandia and Laurentia (Figure 9.7) were observed over two decades ago (Gower 1985; Hoffman 1988). The widely accepted extension of the Grenville orogen in Laurentia to the Sveconorwegian orogen in SW Fennoscandia, means that this connection, known as NENA (Northern Europe North America; Gower et al. 1990), has formed an integral part of most reconstructions of Rodinia (e.g. Li et al. 2008; Evans 2009). Correlations between late-Palaeoproterozoic orogenic belts, and the pre-Sveconorwegian growth of these continents, mean that the NENA connection is also generally correlated at least as far back as the formation of the NUNA (a.k.a Columbia) supercontinent (e.g. Hoffmann 1997; Zhao et al. 2002).

Whitmeyer & Karlstrom (2007) present a comprehensive tectonic model for the continental growth of Northern America during the Proterozoic; in this model, Laurentia grew along its southern margin from 1.8-1.0 Ga by progressive addition of dominantly juvenile arcs and oceanic terranes, in a setting analogous to modern day Indonesia. Crustal provinces in southern Laurentia include the Yavapai province (1.80-1.70 Ga) accreted during the 1.71-1.68 Ga Yavapai orogeny; the Mazatzal province (1.70-1.65 Ga) added during the 1.45-1.30 Ga tectonic event associated with A-type intracratonic magmatism; and the Llano-Grenville province (1.30-1.00 Ga) added during the 1.30-0.95 Ga Grenville orogeny (Whitmeyer & Karlstrom 2007).

In the easternmost part of the Grenville Province, crustal provinces include pre-Labradorian (1800-1770 Ma), early Labradorian (1680-1655 Ma), Mid-to late-Labradorian (1650-1630 Ma), Pinwarian (1520-1460 Ma), Mid-Grenvillian (1040-1020 Ma) and late to post-Grenvillian (1000-940 Ma) events (Gower et al. 2008). This crustal province, which is the closest spatially in Laurentia to Fennoscandia (excluding Greenland), has a strikingly similar history to that of SW Fennoscandia. Telemarkian magmatism in Fennoscandia has a direct correlation with the Pinwarian event, which also involves arc magmatism built upon Labradorian crust (Gower 1996; Gower et al. 2008). Further south, the Muskoka domain in the southwestern Grenville Province also has a striking similarity to Telemarkian events, with coeval to younger continental arc magmatism from 1480 to 1430 Ma, which involves intra-arc extension and contemporaneous A-type magma generation in a back-arc environment (Slagstad et al. 2004). The extent of Telemarkian age crust in Laurentia is extended across the continent by isotopic mapping using Nd model ages; Dickin & Higgins (1992) suggest a vast region of the central Grenville Province was part of a 1.5 Ga crust-forming event.

Figure 9.7. 1.8 - 1.0 Ga Crustal provinces in Laurentia and Fennoscandia (after Karlstrom et al. 2001).

As well as Fennoscandia, Laurentia is correlated eastward with Greenland and parts of the British Isles. The 1.9-1.78 Ga Makkovik province in the easternmost part of the Grenville Province is related to a continent margin setting with both juvenile Palaeoproterozoic and reworked Archaean components (Kerr et al. 1996; Ketchum et al. 2001). The Makkovik province is correlated with the

Ketilidean province of southern Greenland, which is a dominantly juvenile arc located on the edge of an Archaean domain (Chadwick & Garde 1996; Garde et al. 2002). Makkovikian-Ketilidean and pre-Labradorian provinces are correlated with the ~1.75 Ga Rockall Bank (Morton & Taylor 1991), the Rhinns complex in the Inner Hebrides (Muir et al. 1994), and the Annagh gneiss complex in Ireland (Menuge & Daly 1994). These dominantly juvenile belts which formed on the exterior of Palaeoproterozoic and Archaean domains are broadly correlative with the formation of the Transcandinavian Igneous Belt on the southwestern edge of the Fennoscandian continent.

### 9.6.1.2 Amazonia

The Amazonian craton comprises an Archaean core which is flanked to the southwest by successively younging Palaeo- to Mesoproterozoic lithotectonic domains, this feature is similar to that of the Fennoscandian Shield, and has led to correlations being made across the two continents (Geraldes et al. 2001; Cordani et al. 2009; Johansson 2009). The major geological provinces are: Central Amazonian (CAP - >2.3 Ga), Maroni-Itacaiúnas (MIP – 2.2-1.95 Ga), Ventuari-Tapajós (VTP – 1.95-1.80 Ga), Rio Negro-Juruena (RNJP – 1.8-1.55 Ga), Rondonian-San Ignácio (RSIP – 1.55-1.3 Ga) and Sunsás (SP – 1.3-1.0 Ga) (Tassinari et al. 1999). The VTP, RNJP and part of the RSIP represent a vast area of juvenile continental crust that was formed by accretion of magmatic arcs, whereas the younger domains are dominated by crustal reworking (Tassinari et al. 1999; Geraldes et al. 2001). The 1.55-1.30 Ga Rondonian-San Ignacio province involves a collisional orogeny involving a possible microcontinent, accretionary belts, and inboard plutonism (Cordani et al. 2009); a distinct correlation can be made with events of this age in Fennoscandia.

## 9.6.1.3 Australia

During the amalgamation of Rodinia, eastern Australia is typically connected to Laurentia either in the western US (AUSWUS, Karlstrom et al. 1999, 2001) or in northern Canada (SWEAT, Dalziel 1991; Hoffman 1991). A link between these continents is also made for the Nuna supercontinent, in which Australia is typically placed in a SWEAT–type position to the northwest of Laurentia (Betts et al. 2008). Palaeomagnetic data suggest Australia and Laurentia were contiguous from 1730-1595 Ma, but also permit a continued association until ~1200 Ma (Payne et al. 2009). However, a 1.6-1.5 Ga hotspot track in eastern Australia suggests that Laurentia and Australia diverged during this period, with Laurentia staying at low latitudes, and Australia drifting to high latitudes (Betts et al. 2007). Events in the 1.8-1.6 Ga period are particularly linked across Australia and Laurentia. In this period episodic orogenesis occurred along the southern margin of the Australian continent above a north-dipping subduction system, with the pattern of accretion suggesting southward migration of the subduction zone via slab rollback and oceanward stepping behind accreted blocks (Betts & Giles, 2006). Episodes of accretion that link Laurentia with Australia include the ~1780 Ma Yapunka-Yamba-Bow Medicine orogens, the ~1.74-1.7 Ga Strangeways-Kimban-Nimrod-Yavapai orogens, and the 1.65-1.64 Ga Leibig-Kararan-Maztazal orogens (Betts et al. 2008). Some of the

evidence used to infer a subduction zone setting on the southern margin has been refuted (Payne et al. 2010); instead convergence may have occurred under the eastern margin of the continent (Payne et al. 2009). The 1.5-1.4 Ga period is host to extension, basin formation and anorogenic magmatism (Betts & Giles 2006; Wade et al. 2007). After 1.5 Ga the South Australian Craton (Mawsonland) is postulated to have broken away from the North Australian Craton, and then to have reattached during the 1.33-1.1 Ga Albany-Fraser-Musgrave orogenies (Giles et al. 2004). The Australian continent appears to have had a more complex history of accretion, orogenesis and break-up than the southern margin of Laurentia and its extension into Fennoscandia; during the 1.8-1.5 Ga period it can still be considered to be part of an accretionary orogen, but a part which featured more recycling of older crust than juvenile addition (Betts et al. 2008).

### 9.6.1.4 China

China is split into two cratons, the South China Craton (SCC) and North China Craton) NCC; the SCC appears to be poorly constrained in terms of its Proterozoic history and lacks palaeomagnetic key poles, it therefore doesn't feature in some Nuna supercontinent reconstructions or has an unconstrained placement (e.g. Zhao et al. 2002). The NCC comprises two separate blocks, namely the Western Block and Eastern Block; these two blocks amalgamated in the late Palaeoproterozoic at ~1.85 Ga, forming the Trans-North China Orogen (Zhao et al. 2001; 2002; Santosh 2010). The NCC is included in the Nuna supercontinent in a variety of positions; some models have connected the Trans-North China Orogen with other Palaeoproterozoic orogens such as those in India (Zhao et al. 2004, 2006), whereas others have connected the Northern Hebei orogen that forms the northern margin of the NCC with other Palaeoproterozoic orogens (Kusky et al. 2007 GR, Kusky & Santosh 2009; Santosh 2010).

The 1.8-1.4 Ga Xiong'er belt in the southwestern margin of the NCC is interpreted by some to occur in a continental rift environment (Zhao et al. 2002; Peng et al. 2008), whereas others advocate a continental margin setting (Zhao et al. 2003, 2009; He et al. 2008, 2010). The Xiong'er belt is bounded to the south by the 1.6-1.4 Ga Kuanping ophiolite Complex; combining this with the arc setting for the Xiong'er belt, Zhao et al. (2003) suggest that the southern margin of the NCC was bordered by a 1.8-1.3 Ga subduction related belt. If the accretionary margin postulate is accepted, then the NCC must have faced an open ocean along its southwestern margin for this time period; it therefore seems credible to place NCC in the context of a Nuna supercontinent based on this accretionary margin (see Figure 9.8).

The 1.6-1.2 Ga Zhaertai-Bayan Obo rift zone along the northern margin of the NCC is interpreted to result from fragmentation of the NUNA supercontinent (Zhao et al. 2003). A correlation between 1.35 Ga diabase sills in the NCC with 1.4-1.3 Ga mafic dyke swarms in Laurentia, Fennoscandia, Siberia, Australia and Antarctica (Ernst et al. 2008), led Zhang et al. (2009) to infer that the NCC
was part of Nuna until at least this time. Based on extensional magmatism, others consider the NCC to have been involved in break-up of Nuna by 1.6 Ga (Rogers & Santosh 2002).

#### 9.6.2 Proterozoic supercontinents

The 1.8-1.0 Ga long-lived convergent orogen of Karlstrom et al. (2001) can be extended across at least the Amazonia, Fennoscandia, Laurentia, Antarctica, Australia and North China cratons. This accretionary orogen formed on the margin of these continents after the formation of the ~1.8 Ga Nuna supercontinent. Supercontinents may form by two end-member mechanisms: introversion in which interior ocean floor is preferentially subducted, and extroversion in which exterior ocean floor is preferentially subducted (Murphy & Nance 2003). When a supercontinent breaks-up, the trailing edge of dispersing continents will comprise passive margins flanking relatively new oceanic lithosphere, whilst the leading edges will comprise subduction margins that recycle and accrete older mantle lithosphere that surrounded the supercontinent (Murphy et al. 2009).

The Nuna supercontinent partially broke-up at 1.8-1.5 Ga; after this time the continents dispersed before amalgamating again to form the supercontinent Rodinia at ~1.0 Ga. During dispersal, the 1.8-1.3 Ga global accretionary belt can be interpreted in the context of a leading edge, where it recycled the exterior ocean, and accreting oceanic terranes. During retreating phases of this accretionary belt, oceanward migration of the subduction zone trench must have exceeded migration of the continent, allowing for slab rollback. During advancing phases the oceanward migration of the continent would have recycled any oceanbound terranes and lithosphere in an Andean-type setting. The dominance of arc-related 1.8-1.5 Ga crust, and lack of arc-related 1.5-1.1 Ga crust in Fennoscandia, suggests that the margin was dominantly retreating prior to 1.5 Ga, and dominantly advancing after 1.5 Ga.

The idea of the 1.8-1.3 Ga accretionary orogen acting as a leading edge forms the basis of the supercontinent reconstruction shown in Figure 9.8. This reconstruction is largely based on that of Zhao et al. (2002), which was later modified by Zhao et al. (2004) and Hou et al. (2008a). The major change from this previous model is that the global 1.8-1.3 Ga accretionary belt now includes the southwestern margin of the North China Craton, and the southern margin of Australia and its Mawsonland counterpart. The continents are arranged so that the 1.8-1.3 Ga belt forms an exterior belt encircling the supercontinent; this differs from previous reconstructions in which the accretionary belts have only occurred on one side of the supercontinent (e.g. Zhao et al. 2002; Hou et al. 2008; Bispo-Santos et al. 2008). This postulated reconstruction is not constrained by palaeomagnetic data, but does comprise individual fits between continents and some generalised global fits that have been constrained by palaeomagnetism.

During break-up of the Nuna supercontinent after 1.8 Ga, Laurentia and Fennoscandia likely stayed together to at least 1.25 Ga, (Buchan et al. 2000); Amazonia may also have been connected to Fennoscandia until the Sveconorwegian orogeny (Johansson 2009), or may have broken off earlier to then re-amalgamate at ~1.45 Ga (Bogdanova et al. 2001, 2008). Australia may have stayed connected to Laurentia till the formation of Rodinia (Karlstrom et al. 2001). During the formation of Rodinia, the accretionary belt in Laurentia and Baltica then became host to a global-scale interior orogen, the Grenville Belt. To go from an exterior to interior belt, the supercontinent must have extroverted. This is compatible with the postulated rotation of the East European Craton (Starmer 1996), and collision of Amazonia with Laurentia and the EEC (Johansson 2009; Gower et al. 2008; Li et al. 2008).

Figure 9.8. Late Palaeoproterozoic reconstruction of Nuna. Laurentia - Australia - Mawsonland fit modified from Betts et al. (2008); Laurentia - Greenland - East European Craton - Amazon fit modified from Pesonen et al. (2003) and Bispos-Santos et al. (2008); India - N China, Amazon - W Africa - Laurentia - Siberia - Greenland, and S Africa - Australia - Tarim fit modified from Zhao et al. (2002) and Hou et al. (2008a). The location of the S China block is currently unconstrained.

In this model of extroversion of Nuna to form Rodinia, both continental growth and recycling were focussed along the edges of continents as they consumed oceanic lithosphere during their dispersal. Minor amounts of continental growth will have occurred within the interior of the supercontinent during rifting events; some of this rifting is evident as major radiating dyke swarms, i.e. Mackenzie dyke swarm, which has led to inferences about the role of mantle plumes in the break-up of supercontinents (Ernst & Buchan 2002; Hou et al. 2008b).

### 9.7 Continental growth – a final comment

Whitmeyer & Karlstrom (2007) in their model of Proterozoic growth of Laurentia, present a model of continental growth termed the 'arc-accretion-assembly-stabilization' model, which can be applied to accretionary orogens. This model involves three processes; the first comprises accretion of mafic, intermediate and felsic material from the mantle via subduction processes during the multistage evolution of outboard arcs. The second process involves assembly of a mixture of juvenile terranes and older crustal fragments during a series of orogenic episodes, with the style of deformation being subduction-dominated; this multistage assembly includes continental growth via crustal thickening, tectonic imbrications and further differentiation and modification of crust during suturing. The third process involves stabilisation of continental crust via crustal melting, this melting is initiated by crustal thickening and results in periods of late-orogenic granitoid magmatism that stitch sutures and aid the differentiation of the crust.

The arc-accretion-assembly-stabilization model and the processes described above provide a suitable explanation for the formation of Fennoscandian continental crust. The Archaean domains were formed by 2.5 Ga; whether they were formed by subduction-related or geodynamic processes different to those seen today is an interesting topic, but is outside the realm of this thesis. The 2.1-1.8 Ga Svecofennian period saw the multistage assembly of these Archaean domains along with the assembly of arcs and microcontinents at differing stages of maturity. Orogenesis, crustal thickening and orogenic collapse, meant the Palaeoproterozoic and Archaean domains of Fennoscandia were largely stabilised by 1.8 Ga. Further crustal differentiation occurred during repeated episodes of intraplate, commonly A-type, granitoid genesis; these can be related to lithospheric extension associated with distal effects of convergent margin tectonism, and post-orogenic crustal relaxation. After 1.8 Ga the southwest margin of Fennoscandia involved further multistage accretion of largely juvenile crust; this crust was stabilised and differentiated during Sveconorwegian collisional orogenesis (and possibly Hallandian-Danoplonian orogenesis). Since the Sveconorwegian orogeny, the continental crust of Fennoscandia has only seen minor crustal additions such as those in the Oslo Rift (see Larsen et al. 2008), but has suffered major tectonic (as opposed to magmatic) remobilisation of crust along its margins, i.e. during the Caledonian and Timanian orogenies (see Gee et al. 2008).

In Chapter 1, the apparent episodic nature of continental crustal growth was cited, along with the concept that such apparent episodicity may arise from preservational bias in the rock record. This concept suggests that the dominant setting for producing continental crust is at subduction zone margins, but within this setting there is poor potential for preservation; in collisional settings there is little new crust produced, but this setting has a large potential for preservation; and in extensional

settings there is limited zircon-producing crust formed, and this may also have a poor preservational potential (Hawkesworth et al. 2009). Because of this bias, it is likely that periods when collisional settings were most prolific, i.e. when supercontinents amalgamate, will appear to have the greatest amount of crustal growth. The similarity in peaks of crystallisation age with ages of supercontinents (se Figure 1.1), suggests this concept holds true. The peaks in crystallisation age at 1.9 Ga and 2.7 Ga also match up with peaks in juvenile crustal addition, suggesting there was large-scale formation of crust, as well as reworking in collisional settings.

Using Fennoscandia as an example, we can gain some insight in to this important period. During the 2.1-1.8 Ga period, major crustal additions comprised 2.1-2.0 Ga microcontinents with an undefined history, >2.02-1.83 Ga juvenile arcs, and magmatic addition in continental arcs at 1.89 and 1.8 Ga (Lahtinen et al. 2009). There is a lack of 2.5-2.1 Ga age crust, and few detrital zircons have been found within this age range (Lahtinen et al. 2009); suggesting that crustal formation was limited, and that any such crust produced was not preserved. This gap in the 2.5-2.1 Ga period correlates globally (see Figure 1.1). Using the preservation bias concept (Hawkesworth et al. 2009), this period likely involved a lack of collisional orogenies, this in turn can be interpreted as reflecting rifting of the Superia and Slavia cratons (Bleeker 2003). The 1.9 Ga peak in zircon crystallisation ages (and juvenile crustal addition) has previously been linked to a mantle superplume (Condie 2002), but the width of the peak and the existence of a number of individual peaks within the zircon record (Condie et al. 2009), means that a single plume event cannot explain the data. It is suggested that the apparent increase in crustal growth is likely a consequence of both preservation bias during amalgamation of the Nuna supercontinent, but also of increased production of 2.1-1.9 Ga crust via tectonic switching in retreating accretionary orogens that formed just prior to collision. Apparent episodicity of crustal formation is a result of preservational bias that can be linked to formation and break-up of supercontinents on a global scale, but on a regional scale can be linked to episodic migration of subduction zone margins.

Accretionary orogens are the dominant setting for growth and differentiation of continental crust; modern examples can be found in the western Pacific (mainly retreating) and in the eastern Pacific (i.e. Andes; mainly advancing). Ancient examples may have been completely recycled by younger events, however, well-preserved examples exist from a variety of ages (e.g. the 1.8-1.1 Ga belt of SW Fennoscandia and Laurentia, the 1000-325 Ma Central Asian Orogenic Belt, and the 515-330 Ma Tasmanides of eastern Australia); each of these provide a 'tectonic dynasty' for the study of crustal processes (see Åhäll & Larson 2000 and references within).

#### 9.7.1 A final comment on the final comment - continental versus crustal growth

Discussion within this thesis has involved settings, rates and relative amounts of continental growth. It is important to highlight that in the context of this study, continental growth refers to localised addition of juvenile mantle-derived material to the continental crust. Such addition does not imply a net addition to the volume of global continental crust, since at any one time the loss of continental crust globally may outweigh the addition of continental crust. Also, within the context of continental crust, this study has not considered the lithospheric mantle. There is evidence that the sub-continental lithospheric mantle (SCLM) under a large proportion (>70%) of the continental crust is Archaean in age (Begg et al. 2009; Griffin et al. 2009); suggesting that Archaean SCLM has a higher preservation potential than young continental crust. If global crustal growth models account for both the SCLM and the overlying continental crust, the increase in crustal volume since the Archaean will be near zero (Begg et al. 2009).

# Appendix

## **XRF** methodology and precision

Samples were prepared for XRF analysis by removing their weathered surfaces, broken up using a mechanical jaw-splitter, crushed to a coarse powder using an engineer's fly press, and milled to a fine powder in agate pots. At the University of Leicester samples were analysed on a Philips PW1400 X-ray fluorescence spectrometer (sample numbers SA3-XX) or a PANalytical Axios Advanced XRF spectrometer (sample numbers SA7-XX and SA8-XX). There was no significant difference between results from the two instruments.

Loss on ignition was determined from powders dried overnight at 105°C, then ignited at 950°C for 1 hour. Major elements were determined on fused glass beads prepared from ignited powders, with a sample to flux ratio of 1:5, 80% Li metaborate: 20% Li tetraborate flux; the results are quoted as component oxide weight percent, re-calculated to include LOI. Trace elements were analysed on 32mm diameter pressed powder briquettes, prepared from 10g fine ground powder mixed with ~20-25 drops 7% PVA solution and pressed at 10 tons per square inch.

Components with concentrations below the lower limit of detection reported as bdl. LLDs calculated from  $3-\sigma$  for the background determination. At the Norwegian Geological Survey, samples (sample numbers MMxxxxxx and ROGxxx) were analysed on a PANalytical Axios Advanced XRF spectrometer using methods similar to those above, and on a Finnigan MAT ICP-MS (Y, Zr, Nb, REE, Ta, Hf, Th and U), see Flem et al. (2005) for full description of the methods.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            
                                                                                                     |  |         |         |         |         |                    |                               |       

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1526<br>1536<br>1525<br>1527<br>1527<br>1528<br>1528<br>1506<br>1528<br>1518<br>1522                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1526<br>1526<br>1527<br>1527<br>1527<br>1527<br>1527<br>1528<br>1528<br>1518<br>1518<br>1518<br>1516<br>1516<br>1516<br>1516<br>151                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |      

   1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1       1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <ul> <li>94 151.</li> <li>94 151.</li> <li>99 150.</li> <li>91 151.</li> <li>93 150.</li> <li>93 151.</li> <li>93 151.</li>
